We appreciate the reviewers' close reading of the text, and have incorporated the reviewers' constructive criticisms in our revised text, which resulted, we think, in a much better paper. Our responses to the reviewer comments are in blue. The paper is changed substantially in response to the reviewers, consistent with major revisions, including changing the title and reorganizing the emphasis and order of the figures.

Anonymous Referee #1

Received and published: 21 April 2015 General comments: The authors must be congratulated on analysing a large number of datasets and making a useful evaluation for the ESM community. However there are several issues with the paper.

We appreciate the positive comments on the paper, and incorporate the reviewer's constructive criticism into our modified text. We have added numbers to the reviewer's comments, to better facilitate discussion.

1. First of all the paper is plagued with grammatical and syntactical errors, making it awkward to read and repetitive. Many paragraphs need to be completely re-written. I understand how difficult it is for a non-native English speaker to write a paper, but it is no justification for this many errors.

We have worked hard to improve the quality of the writing for the resubmission.

2. Secondly, I find the evaluation on the historical runs to lack originality. Anav et al. 2013 has already addressed the ability of ESMs at reproducing LAI in the high Northern Hemisphere and Mao et al. 2013 attributed the relevant driving mechanisms to the change in LAI globally. Both papers used the satellite product that the authors included in this evaluation. It is hardly surprising to read that models overestimate LAI in the NH, as this has been shown before. I also can't believe the results over the tropics, as satellite has been shown to saturate leading to lower LAI values that reality. Many other comparisons between models and satellite derived LAI are contained here:

http://www.mdpi.com/journal/remotesensing/special_issues/monitoring_global

We agree that the historical part of the analysis is not meant to stand alone, but rather to provide context for the future studies. We have retitled the paper to focus on the future simulations, and restructured the text to focus on the future simulations.

We cite the above-mentioned studies, as well as other studies, to show the connection of our study with previous historical analysis, and try to reduce the amount of discussion of the historical analysis. However, this paper does have to repeat some of the previous work in order to set the context for the rest of the paper.

3. Thirdly, there is no reason why a model that performs well in the historical run also does it for future scenarios. Important factors such as the representation of vegetation dynamics and the effects of nutrient limitation may play a more important role in the future may lead to biases in models that currently perform highly. For example all IPSL modules are ranked highly but non include a full N-cycle

module. Another example, models that include prescribed vegetation tend to perform better, but there is no reason to believe ecosystems will remain in the same place over the future. A shift in vegetation may lead to rapid changes in LAI.

This is an interesting assertion. We would argue that it is very common in considering future trends in variables predicted by models, to evaluate the ability of the models in the current climate (e.g. the whole of Chapter 9 of WG1 of AR5), and to use that information to reduce the uncertainty in the future projects (two examples for the carbon cycle are: Hoffman et al. 2014, Cox et al., 2014, as cited in our manuscript). Therefore we think it is justified to take that approach here. Indeed, only in the mid-latitudes is the reviewer correct for the current set of CMIP5 models that there is no correlation between current skill and projections: in high latitudes and tropics there does seem to be a correlation. Please note that we also consider the CO_2 fertilization of the models, which is a proxy for whether N is included, so we can test this hypothesis that this is important.

On the other hand, for the IPCC, they did not chose to use skill in the current climate to restrict the spread in the future spread of the physical climate projections (i.e. Chapter 9 influence on Chapters 10, 11 and 12 was not strong!), for many reasons, some political and some scientific. The scientific reasons were discussed in some detail in the last sections of Chapter 9, so we add in some discussion of this interesting point in the appropriate section of the paper (old Section 4.2).

The way that we have restructured the paper also makes this less of a focus of the paper, and we show the results both ways.

Finally, the issue of CO_2 fertilization and the relationship of that with LAI is an interesting one. We had assumed, similar to the reviewer that CO_2 fertilization would drive many of the LAI changes. We expand this section of the text to show the decoupling of vegetation carbon and LAI in the future simulations, as well as add a discussion of why carbon uptake SHOULD be decoupled from LAI in many ecosystems and conditions, based on basic scientific understanding. We add a coauthor (C. Goodale) to improve our discussion of this point.

- 4. Next, only one RCP (8.5) was analysed. With the data been available for all four RCPs I don't see why this was not done. The paper would benefit from comparing the response of LAI to the drivers in the different scenarios (i.e. does LAI response in the same way to climate in all RCPs?) We agree with the reviewer that this is a nice addition to the paper, so also consider the RCP4.5 in the revised text and figures, although there are fewer models which completed this experiment (RCP8.5 was the most commonly completed).
- 5. There are several methodological mistakes. The way the growing season (GS) is calculated is poor. There are plenty of papers that use simple methodologies (e.g. Murray-Tortarolo et al. 2013) that can account for changes in GS trough time. The assumption that precipitation only plays an important role in the three months before the growing season in simply wrong, particularly over the tropics, but also for the boreal forest (where autumn browning has been linked to drought later on the year). The authors claim the results for the correlation of climate and LAI are the same annually than over the GS, but show no evidence for this.

We agree that the way we have defined growing season isn't adequate, and because we do not have the space to fully consider multiple growing season definitions, we remove the text from the current manuscript considering growing season, and just focus on the annual averages. Using just annual averages has some problems as well, as discussed in the text, but think is justified for a first study of future LAI changes, and still results in some interesting results. We add in caveats about this point in the relevant sections of the methods and results.

- 6. The authors' definition of drought based on LAI is simply wrong, drought can only be defined based on climate; additionally low LAI can be driven by fire and disturbance and having drought 1/6 of the time is ecologically implausible. We replace the word 'drought' in the manuscript with 'Low LAI', since we still think the concept is very important.
- The inclusion of Kenya in the analysis seems completely out of the blue. We thought a concrete example would help the analysis, but remove the example following the reviewer's comment.
- 8. All figures need to be improved as they are poorly and inconsistently formatted. We have reformatted all the figures, as noted also below. Please note that the figures we had formatted for the final version of the paper (assuming A4 rectangular size) were reformatted as square for the discussion version, which forced the copy-editor to leave a great deal of white space around the figures. This won't be the case in the final version of the paper.
- 9. Generally the paper feels like a collection of preliminary results that have not been properly analysed. A more in depth analyses are needed and simpler graphics and tables would greatly benefit the paper.

We have removed some of the more complicated figures and tables, to improve the accessibility of the paper, and rewrote the results to make them easier to grasp. We have added more synthesis-type graphs, especially with respect to the RCP4.5 contrast to RCP8.5.

Particular comments Tables:

- 10. Tables 3, 4a, 4b, 4c are difficult to read as they contain too many metrics. A simpler approach is needed to facilitate the results to the reader. Table 6 is highly irrelevant. We have moved Tables3, 4a-c into the Appendix. Table 6 is very relevant, as it shows that the spread decreases if the top-models are used for the tropics, which we think is interesting.
- 11. Figures :Figures are badly formatted, difficult to read (some I would say impossible) and generally seem to be missing a more in depth-analisis.Figure 1 has been shown before in the literature many times. Figure 1b seems to be missing parts of the planet.We agree that Figure 1 has been shown many times and move this figure to the supplemental material.
- 12. Figure 2 impossible to read, as are figures 5 and 6. The reviewer does not find probability density function plots easy to interpret,

while we find them wonderful for efficiently conveying substantial information. To accommodate the reviewer and other readers like the reviewer, we have either removed these figures or put them into the Supplement, and replaced them with simpler plots.

- 13. Figure 3 has been shown before in the literature (or similar). We agree that this has been shown previously, and cite the previous work, and move this figure into the Supplement
- 14. Figure 4 does not include all ESMs, not even a ESM that is comparable to CLM. The first statement is true, as it is trying to show an example, but the second statement is not true, as indicated in the figure caption. We have removed this figure in the rewrite in any case.
- 15. Figures 8-11 are poorly formatted and clearly contain many mistakes (e.g. saturation of the legend). Figure 12 is unreadable. Figure 13 contains is poorly formatted

We reformat these figures, and reduce the saturation of the legend. We move the probability density function in Figure 12 into the Appendix, and replace with a line plot. Please note that the legend is saturated when the changes are greater than 8 (now) in standard deviation units, which means it is very statistically significant, so it's probably ok to have the legend saturate at some point. We try to make this point more clear.

16. Abstract Generally I feel the abstract is poorly written. While it does explain in detail the motivations of the authors, nothing is said on the methodology and the formulation of the main results is very ambiguous. I am also missing the key point of the paper as the last line of the abstract.

We rewrite the abstract to accommodate the comments of the reviewer, as well as the updated emphasis of the text.

17. Particular comments: Plant Canopy: Canopy is understood as part of the plan community or the ecosystem, not of a single plant. Needs rewording. Objective (3): interannual variability of LAI Lines 21-23: awkwardly written Lines 29-31: last sentence is out of place.

We replace 'a' with 'the' in front of plant canopy. We rewrite the sentences that are considered awkward by the reviewer.

- Introduction: Generally the introduction is poorly written and needs to be corrected for grammatical and syntactical errors. We re-edit the introduction to improve the writing.
- 19. There are also many fundamental theoretical errors (e.g. Line 7: "Carbon Cycle Modules" should state Land Surface Schemes, as it CCM can also refer to ocean; LAI is not a land C variable, but a vegetation parameter.). In our model (the CLM), LAI as well as vegetative phenology is predicted in the carbon model, but we rewrite the sentence to accommodate the reviewer and the re-emphasis of the paper.
- 20. I am also missing key literature such as: Anav et al. 2013 J. Climate, Sitch et al. 2015 Biogeosciences and Kala et al. 2014 J. of Hydrometeorology. Thank you for bringing to our attention these papers. We have added these papers

to the relevant sections in the introduction and other parts of the paper.

21. Missing the discussion on how LAI is represented on the models (i.e. prescribed vs. dynamic)

These models all predict LAI, which is why we are evaluating them and looking at the projections. We hope with the rewrite that this point is clear.

- 22. Missing all arguments regarding satellite uncertainty (e.g. satellite saturates over high-dense forest, leading to lower LAI estimates) We add a discussion of satellite saturation over high density forests, leading to a lower LAI estimate in the Results section.
- 23. Methods: There is really no need to explain what CMPI5 is. We rewrite the introduction to CMIP5 to be more brief.
- 24. The definition of growing season is poor. Other simple approaches lead to better results (e.g. Murray- Tortarolo et al. 2013 remote sensing).As discussed above, we remove the growing season analysis to focus the paper better.
- 25. Several paragraphs correspond to the introduction. â A 'c In order to make our methods flow better, we repeat some information in the methods section. Unfortunately, it is unclear which part of the methods the reviewer did not appreciate, so we cannot directly comply with this recommendation, but we try to improve the writing in the methods section and make it more succinct.
- 26. Informal English used in many sentences. â'A 'c We edit the text to remove informal English.
- 27. The inclusion of CLM (a DGVM is not justified in the introduction), also why not using JULES and ORCHIDEE?

The CLM is not used as a DGVM here (that is not the default version of the model: see Table 1), but rather as a carbon model. We use the CLM because that is the model we work with. We use it only as an example model, and as appropriate indicate that any model results using this model are just examples.

- 28. The LSM is the same in the coupled and uncoupled runs. â A 'c Yes, this is correct.
- 29. Murray-Tortarolo and Anav et al. 2013 proved that the selection of the LSM is more important for the correct representation of LAI than the climate relationship. Using only one DGVM for comparison is misleading. Our results are quite consistent with Murray-Tortarolo and Anav, in showing that for temperature effects as well as mean and seasonality in LAI, the model is most important. The only place where we find that meteorology matters is for the precipitation relationship, which was not examined in those papers. We make this more clear. Please note that CLM is not a DGVM as used here. Because we reduce the historical portion of this paper, we largely remove this part of the paper, and just put it in as a note in the methods section.
- 30. The definition of drought is poor. Low LAI can also be driven by fire and disturbance

(real-world). Drought cannot be defined based on vegetation but only on climate. As discussed above, we replace 'drought' with 'Low LAI'. For the purposes of the humans or animals trying to use the land biomass to live, it doesn't really matter the cause of the low LAI, so we keep this analysis in the paper. We add in a little more introduction to why we want to use low LAI to indicate whether ecosystems or humans dependent on ecosystems might be at risk. Results:

31. Poorly written. Some results are hardly surprising (e.g. LAI is higher in the tropics). Can't believe model overestimation over the tropics. There is no discussion of satellite errors over highly-dense vegetation.

We add a discussion of model errors over highly-dense vegetation. We refer to previous studies and reduce this part of the paper, as well as rewrite the text.

32. Seasonal cycle is usually defined as max-min LAI.

For most climate variables, the seasonal cycle size is evaluated as the std deviation of the monthly means(e.g. Glecker et al., 2008). In order to make this analysis more consistent with climate variable analysis, so that, for example, it can be incorporated into the model-data comparisons in future IPCCs, we try to make the LAI comparison more similar. We add in this explanation in the text.

- 33. No discussion of why some models over or under predicts SA, IAV and LAI. Was this related to the inclusion of vegetation dynamics? N-dep? Own climate? Because the emphasis of this paper is on the future projections, and how current skill might relate to future projections, we do not have space to consider the causes of the errors. However, as stated previously, there have been many papers considering these issues in detail, so therefore we cite these papers.
- 34. Climate-LAI relationships have been explored in detail before (e.g. Mao et al. 2013) We cite in more detail the Mao et al., 2013 and other papers here.
- 35. Murray-Tortarolo does not compare LAI-precipitation metrics. We clarify the text.
- 36. The analysis of East Africa is out of the blue and not justified or intro- duced anywhere before. They feel unnecessary for the evaluation of global ESMs. We remove this analysis to reduce the bulk of the paper.
- 37. Thirdly, there is no reason why a model that performs well in the historical run also does it for future scenariosThis is an important point that we discussed above and in more detail in the paper, and may just be a difference of believe, rather than of science. We think it is

important to consider *whether* there is a relationship.

38. Summary and conclusions: Repetitive. Not summarizing the main results clearly We have rewritten the summary and conclusions to more clearly bring out the main results.

Anonymous Referee #2

This paper compared multiple earth system models, and Leaf Area Index in these models is the focus of this paper. These caparisons are valuable for the research community. However, the writing of this paper should be improved. The authors need to do more work to make the results easier for readers to understand, and the main conclusions easier for readers to capture.

We appreciate the positive comments from the reviewer, and made the results easier to understand.

Some detailed comments: 1) The abstract is too long, and not good for readers to get the main take-home message from this paper. We rewrite the abstract to better synthesis the results of the paper.

2) The fonts in the figures are so small that they are almost illegible. We reformat the figures to make the fonts larger.

3) The authors produced a lot of numbers in the tables and lines in the figures; but these numbers and figures were not summarized effectively, only making the readers confused. We reformat the figures to make them easier to understand, present that tables as figures, and rewrite the text to summarize the results more effectively.

4) Some sentences in the introduction were unnecessarily repeated in the conclusion part. We rewrite the conclusions to more effectively communicate the main points of the paper.

1 Abstract

| 2 | The <u>area</u> of leaves in <u>the</u> plant canopy, measured as leaf area index (LAI), modulates |
|----|--|
| 3 | key land-atmosphere interactions, including the exchange of energy, moisture, |
| 4 | carbon dioxide (CO ₂), and other trace gases <u>and aerosols</u> , and is therefore an |
| 5 | essential variable in predicting terrestrial carbon, water, and energy fluxes. We |
| 6 | examine LAI projections from the latest generation of Earth system models (ESMs) |
| 7 | for the Representative Concentration Pathway (RCP) 8.5 and RCP4.5 scenarios. On |
| 8 | average, the models project increases in LAI in both RCP8.5 and RCP4.5 over most of |
| 9 | the globe, but also show decreases in some parts of the tropics. Because of projected |
| 10 | increases in variability, across broad regions of the tropics, there are more frequent |
| 11 | periods of low LAI. Projections for both RCP8.5 and 4.5 produce similar LAI trends, |
| 12 | with reduced magnitude for RCP4.5. Projections of LAI changes varied greatly |
| 13 | among models: some models project very modest changes, while others project |
| 14 | large changes, usually increases. Projected increases in LAI generally occur in the |
| 15 | same regions that are projected to experience increases in precipitation. Modeled |
| 16 | LAI typically increases with modeled warming in the high latitudes, but often |
| 17 | decreases with increasing local warming in the tropics. The models with the most |
| 18 | skill in simulating current LAI in the tropics relative to satellite observations tend to |
| 19 | project smaller increases in LAI in the future compared to the average of all the |
| 20 | models. Using LAI projections to identify regions that may be vulnerable to climate |
| 21 | change presents a slightly different picture than using precipitation projections, |
| 22 | suggesting LAI may be useful to the climate change impacts community. |

1 1.0 Introduction

| 2 | Providing future projections of climate change <u>feedbacks and</u> impacts is one of the |
|----|--|
| 3 | goals motivating the development of Earth system models (ESMs). <u>The latest</u> |
| 4 | generation of ESMs includes land models that simulate the temporal evolution of |
| 5 | carbon, <u>and</u> vegetation (Friedlingstein et al., 2006). <u>To do so, these</u> models predict |
| 6 | leaf area index (LAI) and other carbon cycle variables, LAI represents the amount of |
| 7 | leaf area per unit land area, and is an important land carbon attribute. Many ESMs |
| 8 | calculate leaf-level carbon and water fluxes, which are then scaled regionally and |
| 9 | globally based on LAI (e.g. Oleson et al., 2013). The surface energy budget, as well as |
| 10 | plant-based emissions <u>and deposition</u> of aerosols and chemically <u>or</u> radiatively |
| 11 | important gases, are also sensitive to predicted LAI (e.g. Oleson et al., 2013). |
| 12 | Therefore, small errors in simulated LAI can <u>become</u> large errors in many ESMs' |
| 13 | biophysical and biogeochemical processes, and changes in LAI alone can change |
| 14 | climate (e.g. Bounoua et al., 2000; <u>Ganzefeld et al., 1998;</u> Lawrence and Slingo, 2004; |
| 15 | Oleson et al., 2013 <u>; Kala et al., 2014). Unlike many biophysical attributes</u> , LAI can be |
| 16 | observed from satellite (Zhu et al., 2013), and thus represents one of the few land |
| 17 | carbon <u>or vegetation</u> variables that can be directly evaluated in coupled models (e.g. |
| 18 | Randerson et al., 2009 <u>; Luo et al., 2012, Anav et al., 2013b).</u> Finally <u>changes in LAL</u> |
| 19 | and the related normalized difference vegetation index (NDVI), can indicate |
| 20 | ecosystem health and natural resource availability. As such, LAI is widely used |
| 21 | within the famine prediction community (Funk and Brown, 2006; Groten, 1993) and |
| 22 | represents a variable that is easy to use in climate impacts studies. Thus it is |
| 23 | important to consider the 21 st century projections for LAI in Earth System Models. |

| 1 | The current generation of <u>ESMs has</u> prepared historical and future scenario |
|----|---|
| 2 | simulations, within the Coupled Modeling Intercomparison Project (CMIP5) (Taylor |
| 3 | et al., 2009). There have been extensive evaluations and comparisons of the <u>future</u> |
| 4 | projections of the land, ocean, at atmospheric carbon cycle in the ESMs in the CMIP5 |
| 5 | (e.g. Arora et al., <u>2013a</u> ; Friedlingstein et al., 2013; Jones et al., 2013). <u>There has</u> |
| 6 | also been <u>comparison</u> of <u>ESM-simulated</u> seasonal variability in LAI <u>against satellite-</u> |
| 7 | based observations for the high latitudes (Anav et al., 2013a; Murray-Tortarolo et al., |
| 8 | 2013), as well as comparisons of LAI and other variables in ESMs across the globe |
| 9 | (Anav et al., 2013b). Additionally, Shao et al, (2013), Mao et al. (2013), and Sitch et |
| 10 | al. (2015) evaluated the relationship between the carbon cycle and other variables, |
| 11 | such as temperature, or LAI, over decadal and longer time scales. These ESM-based |
| 12 | comparisons build on the long history of evaluation of model simulations of |
| 13 | vegetation properties and carbon balance (e.g. <u>Cramer et al., 1999).</u> |
| 14 | Here, we examine ESM projections of future LAI. Most of our analysis |
| 15 | emphasizes the Representative Concentration Pathway (RCP) 8.5, the most extreme |
| 16 | future scenario, and we contrast it with RCP4.5, a less extreme scenario (van Vuuren |
| 17 | et al., 2011) (Section 3). We evaluate both the model mean LAI projected change, as |
| 18 | well as the model mean divided by the standard deviation (e.g. <u>Meehl et al., 2007;</u> |
| 19 | Tebaldi et al., 2011). In addition, we also consider whether LAI projections can help |
| 20 | the climate impact community anticipate regions that may experience increased |
| 21 | climate exposure and risk of increased food insecurity in the future. We consider |
| 22 | both changes in the mean and the frequency of low LAI events, and how this |
| 23 | information compares to precipitation projections, which are commonly used for |
| | |

| 1 | study. Some models submitted multiple versions, at different resolutions or with |
|----|--|
| 2 | slightly different physics (Table 1). Even though some of the models are closely |
| 3 | related (e.g. CESM1-BGC and NorESM-ME), we include different configurations of |
| 4 | <u>the same model.</u> |
| 5 | This analysis examines model mean changes between the current climate |
| 6 | (1981-2000) and future climate time periods (2011-2030, 2041-2060 and 2081- |
| 7 | 2100). To identify the location where models project these changes will be |
| 8 | statistically significant, we analyze the ratio of the mean change to variability; this is |
| 9 | accomplished by dividing the mean changes over 20 year time periods by the |
| 10 | standard deviation over the current climate (1981-2000) and shown in terms of |
| 11 | standard deviation units (e.g. Mahlstein et al., 2012; Tebaldi et al., 2011). Previous |
| 12 | studies have shown that the spatial and temporal scale used to define these changes |
| 13 | can be important for whether these signals are statistically significant (Lombardozzi |
| 14 | <u>et al. 2014).</u> |
| 15 | Changes in LAI variability are also important for understanding the impact of |
| 16 | climate change. For example, in some regions there is a predicted increase in the |
| 17 | mean LAI as well as an increase in the variability. This can lead to an increase in the |
| 18 | length and frequency of low LAI events, even as mean LAI increases. The length and |
| 19 | frequency of these periods matter for understanding the potential for drought and |
| 20 | ramifications for agriculture or ecosystems. To estimate the periods of low LAI and |
| 21 | low precipitation, we calculate the percent of the time during which the variable is |
| 22 | one standard deviation (evaluated in the 1981-2000 time period) below the current |
| 23 | mean (1981-2000). By definition, if the variables have a Gaussian distribution, each |

| 4 | 2.3 Methodology for evaluation of LAI simulation |
|----|--|
| 5 | Several recent studies have used the same new satellite-derived LAI dataset |
| 6 | (GIMMS LAI3g) in land model evaluation (e.g. Murray-Tortarolo et al 2013; Anav et |
| 7 | al. 2013a; 2013b, Mao et al. 2013, Sitch et al. 2015), including some of the same land |
| 8 | models used here. Thus we do not repeat a complete evaluation of model LAI |
| 9 | compared to satellite LAI. We use the satellite LAI dataset to consider whether there |
| 10 | is a relationship between the model ability to simulate LAI in the current climate |
| 11 | and the model climate projections. We use a few basic metrics in this study (Table 2), |
| 12 | which are described briefly below. |
| 13 | Results for the model and observations are evaluated on a 2.5°x2.5° grid |
| 14 | based on the observed temperature data grid (see Section 2.2). For the metric |
| 15 | analysis here, the averages shown are grid-box means, not areal averages. This |
| 16 | allows us to use similar weighting for both the averages and the rank correlation |
| 17 | coefficients, and tends to weight the global analysis towards high latitudes. However, |
| 18 | most of the analysis focuses on regional areas (tropical (<30°), mid-latitudes (>30° |
| 19 | and <60°) and high-latitudes (>60°), where the differences between weighting by |
| 20 | area and weighting by grid box <u>are</u> reduced. |
| 21 | We <u>compare the satellite-based</u> observed (LAI3g) and model-simulated mean |
| 22 | LAI for the current climate (similar to previous studies e.g. Randerson et al, 2009; |
| 23 | Luo et al., 2012; Anav et al., 2013b). The period 1981-2010 is used for this |

Cornell University 8/19/2015 10:53 AM

Deleted:). Uncertainty in precipitation uncertainty is larger and can be as large as 45% in poorly observed regions (e.g. Dai et al., 1997).

| 9 | simulated in the model. The magnitude of the seasonal cycle is calculated as the | |
| 10 | standard deviation of the climatological <u>monthly</u> means at each grid box. <u>This metric</u> | Compatible 140/2045 40/52 AM |
| 11 | is slightly different than how LAI has previously been evaluated in some studies (e.g. | Deleted: month |
| 12 | Anav et al., 2013a; Murray-Tortarolo et al. 2013; Sitch et al. 2015), but is more | Deleted: over 30 years |
| 13 | similar to analyses of other climate variables (Glecker et al., 2008), facilitating | |
| 14 | inclusion of LAI within climate model evaluations. Metrics for the seasonal cycle | |
| 15 | were computed using a spatial average over each region (Table 2: Std. Dev | |
| 15 | were computed points a spatial average over each region (ruble 2. stal. Dev. | Cornell University 8/19/2015 10:53 AM |
| 16 | Seasonal: Model/obs.), For the seasonal cycle, the ability to capture the timing of | Deleted: by |
| 17 | phenology can be important (e.g. Anav et al <u>, 2013a, Zhu et al.,</u> 2013). To analyze this | Deleted: This allows us to consider over broad regions whether the model has too |
| 18 | ability, we computed the temporal correlation of observed and model-simulated | strong or weak of a seasonal cycle. Cornell University 8/19/2015 10:53 AM |
| 19 | monthly means at every grid box, and then averaged over each region (Table 2: | Deleted: . |
| 20 | Seasonal Avg. Corr.). | |
| 21 | To evaluate the models' ability to simulate LAI interannual variability (IAV), | |
| 22 | we consider the magnitude of the interannual variability, which is calculated as the | |
| 23 | standard deviation <u>of annual mean LAI</u> across years at each grid box <u>(e.g. Zhu et al</u> | Cornell University 8/19/2015 10:53 AM Moved (insertion) [10] |

Cornell University 8/19/2015 10:53 AM Moved (insertion) [10]

| 1 | <u>2013</u>). The IAV is then spatially averaged and compared between the model and | | |
|----|--|--|--|
| 2 | satellite observations (Table 2: Std. Dev. IAV: Model/obs.)., <u>We focus our study on</u> | | |
| 3 | IAV, based on the annual mean, but there may be important changes in the seasonal | | |
| 4 | cycle or length of growing season on an interannual time basis, which our simple | | |
| 5 | approach does not consider (e.g. Murray-Tortarolo et al. 2013). | | |
| 6 | Previous studies have examined correlations between temperature and | | |
| 7 | satellite- derived LAI (e.g. Anav et al., 2013a; 2013b, Zhu et al., 2013) or the closely | | |
| 8 | <u>related</u> normalized difference vegetation index (NDVI; Zeng et al. 2013). Observed | | |
| 9 | variations of LAI at high latitudes tend to be dominated by changes in temperature, | | |
| 10 | while the tropics are more dominated by moisture (<u>Anav et al., 2013a; 2013b,</u> Zeng | | |
| 11 | et al. 2013), which is also seen in coupled-carbon climate models for carbon cycle | | |
| 12 | variables (e.g. Fung et al., 2005). In order to understand what may be driving the | | |
| 13 | IAV in the LAI, we calculate metrics to <u>examine</u> the <u>rank</u> correlation between | | |
| 14 | anomalies in LAI and anomalies in temperature, and trends with time. <u>Although</u> | | |
| 15 | correlations do not <u>identify</u> causation, <u>they</u> can <u>identify the strength of</u> relationships | | |
| 16 | among various driving factors. | | |
| 17 | This analysis focuses on the relationship between temperature and LAI for | | |
| 18 | comparing interannual variability in the modeled and observed datasets. Sensitivity | | |
| 19 | studies have indicated that the grid-box level relationship between temperature and | | |
| 20 | LAI is a good indicator of features intrinsic to the model, rather than to the | | |
| 21 | meteorology forcing the model (as seen also in Anav et al., 2013a; Murray-Tortarolo | | |
| 22 | et al., 2013). This was not the case for the relationship between precipitation and | | |
| 23 | LAI. In sensitivity studies conducted as part of this study, we forced the Community | | |

In an ideal world, we would like the models to emulate the same sensitivity of LAI to temperature or precipitation as in the real world. Cornell University 8/19/2015 10:53 AM

Deleted: Similar to Zeng et al. 2013 we assess the rank correlation of temperature and precipitation to leaf area index in the observations but we also look at trends over the last 30 years. At each grid box, a correlation between the annual mean of temperature and precipitation and time (e.g. the trend with time) against leaf area index are obtained for each model and observation. Because the models do not simulate exactly the same climate as observed, we cannot expect the mod ... [19]

| 1 | Land Model (Lawrence et al., 2012; Lindsay et al., 2014), which is the land model | | |
|----|---|--|--|
| 2 | used in the CESM (Table 1), with reanalysis derived data data (Qian et al., 2006; | | |
| 3 | Harris et al., 2013) instead of model derived winds. The LAI-precipitation | | |
| 4 | relationship across IAV was very sensitive to the meteorology used, and thus is not | | |
| 5 | shown or used to evaluate the current climate simulations of LAI. | | |
| 6 | Land use, especially the conversion from natural vegetation to agricultural | | |
| 7 | use, can heavily perturb the mean and evolution of the seasonal cycle and | | |
| 8 | interannual variability in <u>current climate LAI. To determine whether this changes</u> | | |
| 9 | our model evaluation, we exclude grid boxes with more than 50% of agriculture | | |
| 10 | based on Ramankutty et al., (2008). Results of the model evaluation with and | | |
| 11 | without agricultural grid-box were quantitatively and qualitatively similar to those | | |
| 12 | presented here, and thus we include all grid-boxes in this analysis. | | |
| 13 | For ease of interpretation, we present the metrics described above in Figure | | |
| 14 | <u>10, in which higher numbers represent</u> a better simulation, For correlations, this | | |
| 15 | representation is straightforward; 1 is a perfect correlation and lower values | | |
| 16 | represent a worse simulation, For the other metrics that are not correlations, we | | |
| 17 | convert the <u>statistics to values similar ranges to facilitate</u> ease of display. <u>The</u> mean | | |
| 18 | model bias metric (model/obs) <u>is normalized</u> to a value that varies between 0 and 1, | | |
| 19 | with 1 being close to perfect. <u>This approach penalizes</u> models which have too high of | | |
| 20 | a mean equally with model that have too low of a mean, <u>using</u> the following formula | | |
| 21 | (Figure <u>10):</u> | | |
| 22 | | | |

| 9 | 3.1 Future projections | Deleted: 2.4 Methodology for future |
| 10 | | Cornell University 8/19/2015 10:53 AM Formatted: Font:Not Bold |
| 10 | First we consider the model mean projections of change in LAI for RCP8.5, similar to | |
| 11 | analyses for other standard model variables (e.g. Meehl et al., 2007). Across most of | |
| 12 | the globe, LAI is projected to increase through 2081-2100, with small decreases | |
| 13 | projected for parts of Central and South America and Southern Africa (Figure 1). | |
| 14 | The increases in LAI are largest in high latitudes, mountainous regions (e.g. Tibetan | |
| 15 | plateau) and some parts of the mid-latitudes and tropics (Figure 1; for reference, | |
| 16 | mean satellite observed LAIs in the current climate are presented in Fig. S1). Notice | |
| 17 | that in this study we use projections of human land use based on the RCP8.5 or | |
| 18 | RCP4.5, and thus an important human role in future land cover change is driven by | |
| 19 | the assumptions of the scenario chosen for these studies. Generally, for all the RCPs, | |
| 20 | there is less land use and land cover change projected in the future than occurred in | |
| 21 | <u>the past (e.g. van Vuuren et al., 2011; Ward et al., 2014).</u> | |
| 22 | In order to isolate the changes that are statistically significant, for each model | |
| 23 | we divided the change in LAI by the IAV standard deviation. Values over 1 are | |
| | | |

| 1 | considered statistically significant (e.g. following Tebaldi et al. 2011; Mahlstein et al. | | |
|----|--|--|--|
| 2 | 2012). Using this approach, statistically significant changes in LAI start over the | | |
| 3 | high latitudes, and spread over much of the globe with time (Figure 2). By 2081- | | |
| 4 | 2100, the increases in LAI are 8 times as large as IAV over large parts of high | | |
| 5 | latitudes, as well as the Tibetan plateau and some desert regions, indicating large | | |
| 6 | changes (Figure 2c). Part of the reason for these very large normalized LAI values is | | |
| 7 | that they have low IAV in the current climate. A few isolated tropical regions are | | |
| 8 | projected to have statistically significant reductions in mean LAI, such as in Central | | |
| 9 | America and the Amazon basin. | | |
| 10 | Examination of the RCP4.5 shows a similar pattern of an increase in LAI over | | |
| 11 | most of the globe, although lower in magnitude, based on either the mean change in | | |
| 12 | LAI, or the normalized LAI change (Figure 3a and 3b). This result suggests that the | | |
| 13 | pattern of change in LAI, as seen in the literature for temperature or even to a lesser | | |
| 14 | extent for precipitation, is similar across different climate changes, with the | | |
| 15 | magnitude dependent on the magnitude of the forcing (e.g. Mitchell, 2003; Moss <u>et</u> | | |
| 16 | al., 2010). There is a consistent relationship between changes in LAI and | | |
| 17 | temperature across the different time periods for each model; that is, most models | | |
| 18 | and regions show a constant slope between changes in LAI and temperature (Figure | | |
| 19 | 4). Most models even show a similar slope between LAI and temperature for the | | |
| 20 | RCP4.5 as the RCP8.5 (Figure 4). Recognize that the change in temperature is likely | | |
| 21 | to scale with a change in precipitation as well (e.g. Mitchell, 2003; Moss et al., 2010). | | |
| 22 | This similarity in slope for each model across RCPs and time periods breaks down in | | |
| 23 | the tropics for a few of the models, as some show steeper increases in LAI at warmer | | |
| | | | |

Cornell University 8/19/2015 10:53 AM Moved (insertion) [11]

| 1 | temperatures and others shift from LAI increases to declines as warming continues |
|----|---|
| 2 | (GFDL, IPSL, MIROC and MPI models) (Figure 4b). Across the tropics, LAI is |
| 3 | projected to increase in some regions and decrease in others, so small changes in |
| 4 | the relative area of these changes can lead to large shifts in the regional net mean |
| 5 | LAI change. The value of spatial correlations between the RCP4.5 and RCP8.5 mean |
| 6 | LAI change at each gridbox for the 2081-2100 time period is 0.81, 0.70, 0.79 and |
| 7 | 0.89, for the globe, tropics, mid-latitudes and high-latitudes, respectively (averaged |
| 8 | across the models), showing the spatial coherence in the LAI projections between |
| 9 | these two RCPs. Even the models with the lowest spatial correlation between the |
| 10 | two RCPs (GFDL, IPSL, MIROC and MPI) have statistically significant correlation |
| 11 | coefficients of 0.45 or higher in the tropics, where correlations are the lowest. |
| 12 | The models project a wide range of future changes in LAI (Figure 4). One |
| 13 | model (BNU-ESM) projects a large global mean increase of over 1 m ² /m ² by 2081- |
| 14 | 2100. For the other models, projected global mean increases in LAI amounted to 0.5 |
| 15 | m ² /m ² or less. Some models (inmcm4, IPSL, MIROC and MPI model versions) |
| 16 | projected small net decreases in LAI in the tropics (Figure 4). Between model |
| 17 | differences become even more apparent at the grid-box level, with very different |
| 18 | changes in LAI projected by the different models (Figure S2). The spread in model |
| 19 | projections is discussed further below (section 4.0) in relation to whether model |
| 20 | skill at predicting LAI in the current climate can be used to reduce model spread in |
| 21 | these projections (e.g. Steinacher et al., 2010; Flato et al., 2013; Cox et al., 2013; |
| 22 | <u>Hoffman et al., 2014).</u> |
| 23 | |
| | |

| 1 | 3.2 Identifying regions at risk due to climate change |
|----|--|
| 2 | In addition to being important for land-atmosphere biophysical and biogeochemical |
| 3 | interactions, LAI is also one of the few ESM model variables that is potentially |
| 4 | directly usable by the climate impacts community, along with temperature and |
| 5 | precipitation. This is because LAI and the closely related variable, NDVI are used for |
| 6 | identification and forecasting of drought and famine (e.g Funk and Brown, 2006; |
| 7 | Groten, 1993). Thus LAI projections that identify the regions that are most at risk |
| 8 | can help guide and motivate climate adaptation by identifying emergent areas of |
| 9 | vulnerability. The model mean view of the future projections of LAI is quite |
| 10 | optimistic (Figure 1, 2 and 3), however, if variability also increases, some regions |
| 11 | may experience years with lower LAI more frequently than in current climate, |
| 12 | despite having a constant or higher mean LAI. In fact, many regions, especially in |
| 13 | the tropics, are at risk for more Low LAI years (Figure 5). Here we define % Low |
| 14 | LAI as the % of years when the annual average is one standard deviation below the |
| 15 | current mean (Section 2.1). If the variability and mean stayed constant, the % Low |
| 16 | LAI would remain at 16%. More Low LAI years are projected for large areas of the |
| 17 | tropics and subtropics where projected increases to mean LAI are small in |
| 18 | magnitude or negligible (Figure 1c vs 5c, for example). Model mean changes |
| 19 | between the current climate (1981-2000) and future climate time periods indicate |
| 20 | substantial (>2x) increases in the frequency of low LAI in important agricultural |
| 21 | areas (South America, Australia, Southeast Asia, and parts of Southern Africa) |
| 22 | (Figure 5). Increased risk areas in Fig. 5 also coincide, in some cases, with some of |
| 23 | the most food insecure regions of the world (e.g. Brown and Funk, 2008; Field et al., |

| 1 | 2014). Similar to mean changes in LAI, the %Low LAI for the RCP4.5 at 2081-2100 is | | |
|----|--|--|--|
| 2 | similar in pattern and magnitude to that seen earlier in the century for the RCP8.5 | | |
| 3 | <u>scenarios (Figure 3c vs. Figure 5).</u> | | |
| 4 | Next we consider whether using LAI adds information compared to | | |
| 5 | precipitation, which is more traditionally used in climate change impacts | | |
| 6 | assessments (e.g. Stocker et al. 2013; Field et al. 2014). First we consider the mean | | |
| 7 | change in normalized precipitation (Figure 6a) and the % Low Precipitation (Figure | | |
| 8 | 6b), both defined equivalently to the LAI values (Section 2.1; Figure 2c and Figure 5c | | |
| 9 | respectively) for the model simulations considered here. Broadly speaking, the | | |
| 10 | changes in precipitation seem to occur in similar regions as the changes in LAI, with | | |
| 11 | large increases in precipitation over the high latitudes, and decreases over the | | |
| 12 | subsidence zones of the tropics, as seen previously (e.g. Meehl et al., 2007; Tebaldi | | |
| 13 | et al., 2012). Note that requiring the mean change to be statistically significant is a | | |
| 14 | much stricter criteria than just an increase in low LAI, and thus the area identified in | | |
| 15 | the two methods is quite different (Figure 6a vs. 6b). Overlaying the regions from | | |
| 16 | LAI and precipitation which are either one standard deviation below the mean on | | |
| 17 | average in the models (Figure 6c) or see an increase in % Low values (Figure 6d) | | |
| 18 | suggests that LAI and precipitation largely show similar areas being at risk due to | | |
| 19 | climate change, but there are significant regions which do not overlap. This | | |
| 20 | suggests that there is potentially additional information for climate impact studies | | |
| 21 | using LAI projections than using precipitation alone (Figure 6c and 6d). One of the | | |
| 22 | most noticeable differences between LAI and precipitation projections is in in the | | |
| 23 | Mediterranean region where precipitation is projected to decrease, but LAI is not. | | |
| | | | |

| 1 | Conversely, LAI projections suggest that some parts of South America and southern | |
|----|--|---------------------------------------|
| 2 | Africa are likely to experience more stress, which are not identified using | |
| 3 | precipitation. Future studies should consider whether the results of the LAI | |
| 4 | projections are useful for impact studies specifically in these regions. | |
| 5 | | |
| 6 | <u>3,3 Drivers of LAI projections</u> | Cornell University 9/10/2015 10:52 AM |
| 7 | Next we consider what drives the differences in model projections for LAI, using the | Moved (insertion) [12] |
| 8 | example of RCP8.5 at 2080-2100. By correlating temperature and LAI projections at | |
| 9 | each grid box for each model, , we can look for potentially causal relationships | |
| 10 | between model projections of temperature and LAI (Figure 7). This is analogous to | |
| 11 | using a ranked correlation coefficient to summarize the scatter in RCP8.5 points in | |
| 12 | Figure 4, but at each grid box instead of the regional average. There are strong | |
| 13 | positive correlations between model simulated changes in temperature and LAI in | |
| 14 | some regions, especially the northern high latitudes (Figure 7a), suggesting that | |
| 15 | models with a projected larger warming in the high latitudes also simulate larger | |
| 16 | increases in LAI. Higher temperatures may drive higher LAI; higher LAIs may also | |
| 17 | be driving higher temperatures because of the importance of LAI in changing | |
| 18 | surface energy fluxes (e.g. Lawrence and Slingo, 2004; Kala et al. 2014). By contrast, | |
| 19 | there are strong negative correlations across most of the tropics and subtropics | |
| 20 | <u>(Figure 7a).</u> | |
| 21 | The projected changes in precipitation strongly correlated with projected | |
| 22 | changes in LAI (Figure 7b), suggesting that changes in precipitation are correlated | |
| 23 | with the differences in LAI projections between models. This is consistent with the | |

| 1 | model mean analysis (Section 3.1) that showed for most locations, changes in LAI | |
|----|--|---------------------------------------|
| 2 | occur in the same locations as changes in precipitation (Figure 6). Again, because | |
| 3 | LAI changes the surface energy fluxes, there may be a feedback from LAI changes | |
| 4 | (e.g. Lawrence and Slingo, 2004; Kala et al. 2014). The correlations seen in this | |
| 5 | analysis for RCP 8.5 are similar for the RCP4.5 (Figure S3). | |
| 6 | Last, we examine the correlation across models between the modeled | |
| 7 | changes in vegetation carbon stocks and change in LAI between current conditions | |
| 8 | and 2081-2100 (Figure 7c). The relationship between LAI and vegetation carbon is | |
| 9 | not straightforward, and depends on the specific algorithms used in the models. | |
| 10 | Many ESMs calculate photosynthetic rates per unit leaf area; these rates are then | |
| 11 | extrapolated to canopy-level gross primary production using LAI and other | |
| 12 | variables (e.g., light, nitrogen and CO ₂ availability and leaf physiological parameters) | |
| 13 | (e.g., See Bonan et al., 2011, Piao et al., 2013). The simulated increases in LAI are | |
| 14 | correlated across models with simulated increases in plant carbon stocks in many | |
| 15 | low-LAI regions, including many deserts, grasslands, and tundra ecosystems (Figure | |
| 16 | 7c). Leaves compose most or all of the aboveground plant biomass in these | |
| 17 | ecosystems (e.g., Friedlingstein et al. 1999), such that increases in LAI relate directly | Cornell University 8/19/2015 10:53 AM |
| 18 | to increases in plant carbon stocks. Changes in LAI correlate more poorly with | Moved (insertion) [9] |
| 19 | simulated changes in plant carbon stocks in other regions, with small or negative | |
| 20 | correlations in many boreal, temperate, and tropical forested regions (Figure 7c). | |
| 21 | Leaves typically compose only 3-5% of aboveground plant biomass in forests | |
| 22 | (Friedlingstein et al. 1999), and closed-canopy forests can contain widely variable | |
| 23 | stocks of woody biomass that typically depend more on successional status than LAI | |
| | | |

| 1 | or growth rate. Differences in the fractional composition and turnover of these leaf- | |
|----|--|--|
| 2 | and woody tissues should decouple changes in LAI from changes in carbon stocks in | |
| 3 | woody biomass. As an example, in the CLM, the land model for the CESM-BGC, CO_2 | |
| 4 | fertilization causes a larger increase to wood allocation (62%) than to leaf allocation | |
| 5 | (21%) in the Southeastern US (Lombardozzi, personal communication, 2015). <u>Thus.</u> | |
| 6 | the issue of how LAI responds in different models is interesting and should be | |
| 7 | <u>considered in future studies.</u> | |
| 8 | Another important potential contributor to the future projections of LAI is | |
| 9 | the effectiveness of carbon fertilization in the models (e.g. <u>Arora et al., 2013), Using</u> | |
| 10 | <u>the carbon dioxide fertilization factor (β-land) from the Arora et al. (2013) study we</u> | |
| 11 | use a rank correlation to explore the importance of the carbon dioxide fertilization | |
| 12 | strength for predicting future vegetation carbon and LAI across the models. We | |
| 13 | would expect models that respond more strongly with increased carbon uptake | |
| 14 | <u>under higher CO_2 conditions (i.e.</u> larger β -land) to have greater vegetation carbon | |
| 15 | and LAI in the future. Globally the correlation with β -land is 0.46 for vegetation | |
| 16 | carbon and -0.21 for LAI, suggesting that while some of the differences in future | |
| 17 | vegetation carbon projections across models is due to differences in the model | |
| 18 | simulation of CO_2 fertilization, LAI changes are not necessarily related to CO_2 | |
| 19 | <u>fertilization. The β-land correlation for vegetation carbon is 0.29, 0.47 and 0.60 for</u> | |
| 20 | tropical, mid-latitude and high latitude, regions, respectively, while for LAI these | |
| 21 | values are -0.18, -0.09 and 0.21, Thus for high latitudes, especially, the projections | |
| 22 | of LAI appear to be dependent on the way the models' simulate the carbon dioxide | |
| 23 | fertilization in the different models. This could also be, however, an artifact that the | |

Cornell University 8/19/2015 10:53 AM Moved (insertion) [16]

| 1 | two models with the lowest carbon dioxide effect (CESM-BGC and NOR-ESM) use | |
|----|---|---|
| 2 | the same land carbon model (Thornton et al., 2009), which predicts low values of | |
| 3 | LAI in high latitudes for present day and does not tend to increase LAI much in the | |
| 4 | future. These models also have low carbon dioxide fertilization effects, because of | |
| 5 | their nitrogen limitation, which could be driving the correlation between model | |
| 6 | projections of LAI and carbon dioxide fertilization in the high latitudes. It is | |
| 7 | interesting that in the tropics the carbon dioxide fertilization is negatively | |
| 8 | correlated to future LAI changes, and only slightly correlated with vegetation carbon | Cornell University 8/19/2015 10:53 AM |
| 9 | Again, this could be an artifact of having only two related low carbon fertilization | Moved (insertion) [17] |
| 10 | models, as these models see a strong increase in nitrogen mineralization in the | |
| 11 | tropics in a warming climate, which allows an increase in productivity in the future | |
| 12 | tropics (Thornton et al., 2009). In other words, the negative correlation in the | |
| 13 | tropics between LAI projections and CO ₂ fertilization could be due to the smaller | |
| 14 | temperature impact on carbon cycle (γ-land from Arora et al. 2013) in the N-limited | |
| 15 | models (i.e. the β -land and γ -land are negatively correlated in Table 2 of Arora et al., | |
| 16 | <u>2013).</u> | |
| 17 | | |
| 18 | 4.0 Reducing spread in the future projections | Cornell University 8/19/2015 10:53 AM |
| 19 | There are large differences between the different models' projections of | Moved (insertion) [18] |
| 20 | future LAI (e.g. Figure 4; Figure S2; Figure 8b). Previous studies have tried to | |
| 21 | reduce the uncertainty in future projections by looking for relationships between | |
| 22 | model metrics and future projections of climate, and then choosing the models | |
| 23 | which best match the observations in the current climate (e.g. <u>Cox et al.</u> | Cornell University 8/19/2015 10:53 AM Moved (insertion) [19] |

| 1 | 2013;Hoffman et al., 2014) or by subsampling models for different regions by their | |
|----|---|---|
| 2 | performance (e.g. Steinacher et al., 2010). In this section we use both approaches to | |
| 3 | try to reduce the spread in LAI projections at the end of the 21 st century (2081- | |
| 4 | 2100). In essence, we are looking for a correlation between current model | |
| 5 | performance and the future projection, in order to reduce the uncertainty in the | |
| 6 | future projections. In many cases in climate modeling and projections, there is no | |
| 7 | correlation between model skill in current climate conditions and projections (e.g. | |
| 8 | <u>Cook and Vizy, 2006), however in some limited cases there is a correlation between</u> | |
| 9 | metric score and a projection, and one is able to constrain future projections (e.g. | |
| 10 | <u>Cox et al., 2013; Steinacher et al., 2010). Here we consider whether such a case</u> | |
| 11 | applies. In doing this type of analysis, we are making an assumption that model skill | |
| 12 | in the current climate translates into better model projections, which may be a | |
| 13 | product of real model differences or a statistical error. The advantages and | |
| 14 | disadvantages of using this type of approach are discussed in more detail in Flato et | |
| 15 | <u>al. (2013).</u> | |
| 16 | | |
| 17 | 4.1 Evaluation of model LAI | |
| 18 | Several recent studies have evaluated the land models in ESMs using the LAI | |
| 19 | satellite records (e.g. Anav et al. 2013a; 2013b; Mao et al. 2013; Sitch et al. 2015). | |
| 20 | Thus we do not repeat those assessments, but rather briefly summarize the results | / |
| 21 | of the comparisons here. | |
| 22 | Most models tend to overestimate the mean LAI compared to the | / |
| 23 | observations (Figure 9a), and this is true at all latitudes (Figure 9a, Table S2). | / |
| | $\sim \sim $ | |

Cornell University 8/19/2015 10:53 AM Moved (insertion) [20] Cornell University 8/19/2015 10:53 AM

Deleted: We evaluate the mean change in the future using the RCP8.5 scenarios for temperature, precipitation, and LAI (e.g. Tables 3 and 4) using the models listed in Table 1. RCP8.5 is the most extreme scenario in the CMIP5 archive. We use it to identify regions that are most at risk in the future. Areas with mean changes in LAI, precipitation, and temperature that are larger than the historical variability indicate statistically changes to climate and vegetation from current climate. To highlight where models predict these areas will be, mean changes over 20 year time periods are divided by the standard deviation over the current climate (1981-2000) and shown in terms of standard deviation units (e.g. Mahlstein et al. 2012; Tebaldi et al. 2011). The spatial and temporal scale we use to define these changes can be important for whether these signals are statistically significant (Lombardozzi et al., 2014) and we calculate this using a 20-year time scale at the grid ... | 1 | Several models have a large overestimates (>50% too high), including bcc-csm1, |
|--|--|
| 2 | bcc-csm1-1, BNU-ESM, GFDL-ESM2G, GFDL-ESM2M, MIROC-ESM. The <u>over-</u> |
| 3 | prediction relative to the satellite data tend to be larger in tropical regions for most |
| 4 | models, but are also larger in the high latitudes for the GFDL model versions (Figure |
| 5 | 9a, Table S2). However, the satellite derived LAIs have biases; for example, they |
| 6 | underestimate high LAIs due to being unable to see all the leaf layers in closed |
| 7 | canopies or overestimate LAIs in more arid regions, and thus there may also be an |
| 8 | error in the observational dataset (see discussion in Anav et al. 2013b or Pfeifer et al. |
| 9 | 2014, for example). |
| 10 | Some models also tend to over predict the strength of the seasonal cycle (e.g. |
| 11 | bcc-csm1, BNU-ESM, MIROC-ESM) (Figure <u>9b;</u> Table <u>S1</u>), where the strength of the |
| | |

Cornell University 8/19/2015 10:53 AM **Deleted:** overpredict the strength of the seasonal cycle differ. Several models underpredict the seasonal cycle at highlatitudes (e.g. CanESM2, CESM1-BGC, GFDL-ESM2G, GFDL-ESM2M, INMCM4, IPSL-CM5A-LR, IPSL-CM5A-MR, IPSL-CM5B-LR) (Figure 2b, 2h, 2k; Table 4; Anav et al. 2013). The magnitude and direction of bias in model projections also vary by region. For example, one set of models overpredicts the strength of the seasonal cycle in the tropics and mid-latitudes, but underpredicts in the high-latitudes (e.g. bcc-csm1, bcc-csm1_1), while one set of models overpredicts the seasonal cycle at mid latitudes, but underpredicts in the tropics (e.g. MIROC models). Another set of models underpredict the seasonal cycle across all latitudes, but especially the tropics and high-latitudes (e.g. HadGEM2 models). The spatially averaged correlations between the seasonal cycle in the observations and models show a range of between 0.2 to 0.58 (Table 4), suggesting the need for substantial improvement in the timing of the seasonal cycle. Of course, there is not a strong seasonal cycle in the tropics, [23] Cornell University 8/19/2015 10:53 AM Deleted: The interannual ornell University 8/19/2015 10:53 AM Deleted: overpredicted Cornell University 8/19/2015 10:53 AM Formatted: Indent: First line: 0.5" Cornell University 8/19/2015 10:53 AM Deleted: 2c, 2f, 2i, 2l; Cornell University 8/19/2015 10:53 AM Deleted: 4 Cornell University 8/19/2015 10:53 AM Deleted: across the years Cornell University 8/19/2015 10:53 AM Deleted: . | 1 | variability in the annual mean LAI (Figure 9d; Table S1), with the correlations being |
|----|---|
| 2 | strongest in the tropics, and weakest in the high latitudes (Figure 9d; Table 52). This |
| 3 | is likely partly due to the strength of the LAI differences in tropics and its limitation |
| 4 | primarily by moisture alone (with low LAI in the deserts and high LAI in tropical |
| 5 | forests). The timing of the seasonal cycle <u>(Figure 9e; Table S1) is less well</u> simulated |
| 6 | in the models, with several models not having on average a statistically significant |
| 7 | correlation (~0.5 for 95% significance for 12 month seasonal cycle) on the global |
| 8 | scale, or in the mid- and high latitudes (e.g. GFDL, MPI-ESM-MR on global scale, |
| 9 | GFDL, inmcm4 and MPI-ESM-MR for various regions). |
| 10 | Next we explore the observed and <u>modeled</u> relationship between LAI and |
| 11 | temperature and the observed and modeled trend in LAI (e.g. Anav et al., 2013a; |
| 12 | <u>Anav et al., 2013b; Ichii et al., 2002; Zeng et al., 2013; Mao et al., 2013; Zhu et al.,</u> |
| 13 | 2013). As previously shown, there are positive relationships between modeled and |
| 14 | measured LAI and temperature in high latitudes (Figure 7a; Figure S4; e.g. Anav et al. |
| 15 | 2013a; Ichii et al., 2002; Zeng et al. 2013; Zhu et al. 2013). In the tropics (<30°), the |
| 16 | relationship can be positive or negative but some regions tend towards a negative |
| 17 | relationship (Figure <u>\$4; Figure 7a</u>). This is consistent with our understanding that |
| 18 | many places in the tropics are close to the optimal growing temperature already, |
| 19 | and increases may lead to reduced productivity (Lobell et al., 2011), although this |
| 20 | also could be related to moisture stress (Fung et al., 2005). <u>Compared to the</u> |
| 21 | observed correlations, most models have too strong of a negative relationship |
| 22 | between LAI and temperature in the tropics, and too strong of a positive |
| 23 | relationship in the high latitudes (Figure 9f, Table S2a-c). In the tropics, the BNU- |

| 1 | ESM model has a weakly positive impact of temperature, while in the high latitudes, |
|----|---|
| 2 | especially the CanESM2, HadGEM2-CC, HadGEM2-ES, MPI-ESM-MR models have a |
| 3 | much stronger correlation than observed. The model and observations show |
| 4 | similarly weak correlations between the temperature and LAI in the mid-latitudes. |
| 5 | <u>Some</u> regions <u>show</u> substantial trends over time (1981-2010) in <u>measured</u> |
| 6 | LAI (Figure <u>S4b</u>), especially in high latitudes in the Northern Hemisphere, (e.g. Zhu et |
| 7 | al., 2013; Mao et al. 2013). This could be associated with the longer growing season |
| 8 | due to warming (e.g. Lucht et al., 2002; Zeng et al. 2013). It is also possible that this |
| 9 | trend is due to <u>CO₂</u> fertilization effects (e.g. Friedlingstein and Prentice, 2010). For |
| 10 | high latitudes, we find a rank correlation of 0.58 across the models between the CO_2 |
| 11 | fertilization factor on land for the Earth system models (called the <u>B-land in Arora et</u> |
| 12 | al, 2013, as discussed above) and the average correlation of observed LAI with time, |
| 13 | suggesting that there may be a component of carbon dioxide fertilization in the |
| 14 | models' temporal trends. These trends are stronger in the models than the |
| 15 | observations, which may be related to an overestimate of the fertilization effect. |
| 16 | With regard to LAI interannual variability correlations with temperature or time, |
| 17 | that there are also strong correlations <u>among</u> temperature, precipitation and time |
| 18 | themselves (e.g. IPCC, 2007). Here we do not attempt to differentiate these signals |
| 19 | because of the statistical complexity and the shortness of the time record. <u>The</u> |
| 20 | shortness of the record considered <u>could also</u> lead to aliasing of the real variability, |
| 21 | especially in regions like the Sahel <u>that have</u> strong decadal scale variations (e.g. |
| 22 | Loew, 2014), The observational datasets <u>also contain measurement noise</u> , while |
| 23 | the model values do not $_{\!$ |

| 1 | correlations of LAI with the environmental variables in the observations relative to |
|----------------|--|
| 2 | the true values, as seen compared to many models (Figure <u>9f).</u> Thus, our metrics for |
| 3 | interannual variability are likely to be more impacted by uncertainty in the |
| 4 | observations than for the annual mean or seasonal cycle, and thus they may be less |
| 5 | useful for evaluation of the models, although potentially interesting. For this study, |
| 6 | we consider the IAV in the annual mean, but there may be important changes in the |
| 7 | seasonal cycle or length of growing season on an interannual time basis, which our |
| 8 | simple approach does not consider (e.g. Murray-Tortarolo et al. 2013). In addition, |
| 9 | the regional or global average of some of these correlations may be difficult to |
| 10 | interpret, as not statistically significant (e.g. Figure 9f), thus making the LAI IAV |
| 11 | correlations less helpful. |
| 12 | Figure <u>10</u> summarizes our comparisons of the models to the observations for |
| 13 | LAI for the different metrics in Table 2, (Tables S1, S2). In order to show both |
| 14 | correlations and model mean biases in the same figure, we have converted the |
| 15 | model-data comparisons into Model Evaluation Values using equation (1) in Section |
| 16 | 2,3, where 1 is a perfect model simulation and lower values represent worse model |
| 17 | simulations. Overall none of the models <u>does</u> a perfect job, and <u>improving</u> |
| 18 | simulation of LAI for all models <u>will be</u> important. In addition, as discussed above, |
| 19 | some models perform better in some regions than others. In order to more easily |
| 20 | see how the models compare, we also show the ranking of the different models in |
| | each region (Table 3) For this comparison we exclude the magnitude and |
| 21 | cach region (rable 2). For this comparison, we exclude the magnitude and |
| 21 22 | <u>correlations in</u> the IAV, because the observational estimates for this are more likely |
| 21 22 23 | correlations in the IAV, because the observational estimates for this are more likely to be in error than for the annual mean and seasonal analysis, as discussed above. |

| 1 | Thus our overall evaluation of LAI in the models includes the following metrics: |
|----|---|
| 2 | annual mean LAI, spatial correlation of annual mean, standard deviation of seasonal |
| 3 | cycle and temporal correlation of the seasonal cycle. In the tropics the top three |
| 4 | models are the INMCM4, the IPSL-CM5A-LR and the IPSL-CM5B-LR. For the mid- |
| 5 | latitudes the top models are the CanESM2, IPSL-CM5A-MR and the HADGEM2-ES. |
| 6 | For high-latitudes the top models are the BNU-ESM, bcc-csm1 and the MIROC- |
| 7 | ESM_CHEM (Table 3; Figure <u>10</u>). |
| 8 | ▲ |
| 9 | 4.2 Future projections, constrained, by current, model performance, |
| 10 | Across broad regions, we evaluate which metrics are the most useful for potentially |
| 11 | constraining future climate projections by considering how the metric is correlated |
| 12 | with the projections (Figures 9 and 10 ; Tables S1; S2). We consider 4 regions: the |
| 13 | globe, tropics (latitudes<30°), mid-latitudes (latitudes between 30, and 60°), and |
| 14 | high latitudes (latitudes >60°). For the first approach, we look for the metrics that |
| 15 | have the highest correlation coefficient to constrain the future estimate of change in |
| 16 | LAI (similar to Cox et al, 2013) (Figure <u>11a</u> and <u>11b). Using this approach, we look</u> |
| 17 | for the model metrics (from Table 2) which have the highest correlations with |
| 18 | future projections across the models, for each of the regions. If we choose the |
| 19 | models which do the best job with the metrics, this reduces the number of models |
| 20 | included in the projections, and may reduce model spread in projections. |
| 21 | As an example, for the globe, there are two metrics that correlate the highest |
| 22 | with future projections: the average LAI vs. date correlation, and the global mean |
| 23 | LAI ratio of model to observation. This analysis suggests that models with the |

| 1 | largest relative <u>change</u> in LAI over the last 30 years <u>(1980-2010)</u> will have the | 'n |
|----|--|----|
| 2 | largest change in LAI in the future (Figure <u>11a</u>). It also suggests that models with | e |
| 3 | higher LAI in the current climate, will have a larger change in the future (Figure | |
| 4 | 11b). In Fig 11a and 11b, the observation-based estimates are indicated by the gray | |
| 5 | vertical bar. Notice that the projected change in LAI given by models that match best | |
| 6 | with the observations <u>differs</u> for different metrics, and thus <u>it does not allow us to</u> | |
| 7 | uniquely constrain the future projections, <u>(although it does suggest</u> that <u>the highest</u> | |
| 8 | values are the least likely). There is one model with a very large change in LAI in the | |
| 9 | future <mark>, (BNU-ESM)</mark> , which can drive much of the correlation. We use rank | |
| 10 | correlations instead of simple correlations, however, so that <u>these results are</u> largely | |
| 11 | insensitive to the removal of one model. | |
| 12 | For <u>both</u> the tropical region, <u>and</u> in the global analysis, the <u>change</u> with time | |
| 13 | (LAI correlation with date) and the mean model/observation have the largest | e |
| 14 | correlations (Figure <u>11c</u> and <u>11d). Thus</u> models <u>that predict high LAIs</u> in the <u>current</u> | |
| 15 | climate and/or currently have large trends with time, tend to project higher LAI | |
| 16 | changes in the future. Again, these two metrics would constrain our future | |
| 17 | projections to two different LAI values, as they grey lines intersect with the slope at | |
| 18 | different LAI changes (Figure 11c and 11d). For mid-latitudes, the highest | |
| 19 | <u>correlation (and only</u> statistically significant <u>correlation</u>) is <u>between</u> the model | |
| 20 | predicted change in precipitation and LAI (Figure 11e). Thus mid-latitude | |
| 21 | projections of LAI are difficult to constrain based on model metrics, but are sensitive | |
| 22 | to modeled changes in precipitation (as seen also in Figure <u>6).</u> For high latitudes | |
| 23 | there are three metrics with similar correlation coefficients: the average temporal | |

Cornell University 8/19/2015 10:53 AM Deleted: drift...hange in LAI over tl ... [66]

Cornell University 8/19/2015 10:53 AM Deleted: , (as also seen...and in the [67]

1 correlation in the seasonal cycle, the size of the interannual variability and the size 2 of the seasonal cycle in LAI (Figure <u>11f., 11g, 11h)</u>. Unfortunately again, these three 3 metrics suggest a different projected change in LAI when the observed value is used to identify the models that are most realistic (grey line in Figure <u>11f</u>, <u>11g</u> and <u>11h</u>). 4 5 Overall, this analysis of multiple metrics suggests that there is no single metric available that is the most important in all circumstances for improving our 6 7 estimates for the changes in LAI. Thus, deduction of a more probable future LAI projection is not available to us in this case (as opposed to Cox et al, 2013, where 8 9 only one metric is presented). 10 The second approach for reducing spread in the future projections follows the ideas of Steinacher et al. (2010). Here for each region, we chose the models that 11 12 performed the best for several metrics (i.e. using the rankings in Table 3), instead of 13 just one metric at a time (as above). For this study, we chose to use the top half of 14 the models, based on their performance for each region (Table 3), so instead of 15 including 18 models, we include 9 models for each region. Using this approach does 16 change the mean future projections, especially for the tropics and high latitudes (Table 4; Figure <u>8a vs. 8b</u>), and does reduce the spread in the model values in the 17

tropical region, but does not reduce the mean spread in mid-latitudes or high
latitudes (Table <u>4; Figure 8c vs. 8d)</u>, In the tropics, the top models tend to have
lower future projections of LAI than the average of all the models (0.07 m²/m²)
instead of 0.16 m²/m²). This is actually consistent with the analysis in Figure <u>11</u>,
since the models with the higher skill (close to grey line) would tend to have lower
or <u>middle</u> values of future LAI <u>projections</u> (Figure <u>11a,b</u>). For the mid-latitudes,

| 1 | there is not <u>as</u> much difference between using all models or the top performing |
|--|---|
| 2 | models (Table 6), while for high latitudes, the top models tend to project <u>slightly</u> |
| 3 | higher LAI in the future, also consistent with Figure <u>11 (f</u> ,g,h), where the |
| 4 | observations tend to suggest higher LAI projections are more consistent for the |
| 5 | metrics with the highest correlation. |
| 6 | The spatial distribution of the change in the future projections using the all |
| 7 | models vs. the top models is consistent with the mean over the regions, with the |
| 8 | largest change being seen across the tropics, with a reduction in both the mean LAI |
| 9 | projection (Figure 8a vs. 8b) as well as the standard deviation, (Figure 8c vs. 8d). The |
| 10 | changes in mid-latitudes and high latitudes from subsampling only the top |
| 11 | performing models are not very large in most locations (Figure <u>Ba</u> vs. <u>Bb</u>). Only in |
| 12 | the tropics is the spread in the models reduced in the future projections (Figure $\frac{3c}{2}$ |
| 13 | vs. <u>8d). The percent drought in the future is increased in the tropics, if we only</u> |
| 14 | <u>consider</u> the top models (Figure <u>8e</u> vs. <u>8f</u>). |

Our analysis suggests that using multiple metrics does provide information
 that allows us in some cases (especially the tropics) to change our mean future
 projection, and reduce the spread between models predictions. Overall, including
 only the top models in the tropics project a more pessimistic future, with small
 increases in mean LAI, and an expansion in the regions at risk for a low LAI, while at
 high latitudes, it tends to increase the already large increase in mean in LAI.

7

8 5.0 Summary and Conclusions

- 9 LAI is <u>an important term for scaling leaf-level biogeophysical and biogeochemical</u>
 10 processes to regional and global areas, and <u>thus it is vital</u> to <u>consider its change in</u>
- 11 future projections. Here for the first time we consider LAI projections across the
- future projections. <u>Here for the first time we consider LAI projections across the</u>

12 <u>CMIP5 models and find that over much of the globe in the future, the models project</u>

13 an increase in mean LAL in the RCP8.5 scenario over the 21st century. Decreases are

14 <u>projected in the limited regions</u> where there is <u>also</u> a <u>projected</u> decrease in <u>mean</u>

15 precipitation, constrained primarily to the tropics. The change in LAI appears to

16 grow with temperature increases across regions over the 21st century (Figure 4).

17 <u>Changes in LAI projected in the RCP4.5 are largely consistent with changes in</u>

18 <u>RCP8.5, but have a reduced amplitude due to the smaller climate forcing.</u>

19 For assessing climate change impacts, we propose that <u>both</u> mean LAL<u>and</u>

20 <u>LAI</u> variability <u>are</u> important in identifying <u>vulnerable regions</u> in future projections.

21 <u>The models project an increased incidence of Low</u> LAI conditions despite higher

22 mean LAIs, especially in the tropics (Figure 5). While much of the variability in LAI

23 is driven by changes in precipitation, projections of lower mean LAI or Low-LAI

Cornell University 8/19/2015 10:53 AM Formatted: Indent: First line: 0"

Cornell University 8/19/2015 10:53 AM Deleted: Using the example of East [69]

| 1 | incidence can identify a slightly different set of vulnerable regions (Figure 6), and |
|----|---|
| 2 | add to the information that precipitation projections provide. |
| 3 | In order to explore whether we can use model skill in the current climate to |
| 4 | reduce the spread in the future projections (e.g. Flato et al., 2013), we conducted a |
| 5 | brief comparison of the models to available satellite-derived LAI data (Zhu et al., |
| 6 | 2013), similar to previous analyses (e.g. Anav et al., 2013a; 2013b; Mao et al., 2013; |
| 7 | Sitch et al., 2015). Our results support the previously conclusions that the modeled |
| 8 | LAI could be improved in many aspects of the mean, seasonal and interannual |
| 9 | variability, although difficulties in the observational data may preclude definitive |
| 10 | assessment (Figure 9). |
| 11 | We use two different methods for reducing the large spread in future |
| 12 | projections, and find that combining multiple metrics to <u>choose</u> better models (e.g |
| 13 | similar to Steinacher et al., 2010) seems to work more robustly than simply |
| 14 | correlating one metric against future projections (e.g. Cox et al., 2013; Hoffman et al., |
| 15 | 2014), because the different metrics suggest different <u>future projections</u> (Figure |
| 16 | <u>11).</u> Overall, the top performing models (top half of the models from Table <u>4</u>) |
| 17 | suggest smaller future <u>increases</u> in LAI in the tropics, and more regions with <u>more</u> |
| 18 | incidences of low-LAI conditions than assessments that include all the models. This |
| 19 | approach also reduces the spread <u>among</u> models in the tropics. <u>However, using</u> only |
| 20 | the top models, did not make a large difference in projections in the mid- and high |
| 21 | latitudes (Figure <u>8).</u> |
| 22 | Finally, the spread <u>among</u> models' projections of LAI was correlated with |
| 23 | model's projections of precipitation (Figure <u>7b</u> , and Figure <u>6).</u> Thus our projections |

Cornell University 8/19/2015 10:53 AM Deleted: higher vulnerability for food security in these Cornell University 8/19/2015 10:53 AM Deleted: chose Cornell University 8/19/2015 10:53 AM Deleted: values Cornell University 8/19/2015 10:53 AM Deleted: 15). Our results suggest that the better performing models tend to project lower LAIs in the future in the tropics in contrast to (Cox et al., 2013), which focused on carbon-temperature relationships in the Amazon and which showed that observational constraints on the models tend to suggest less loss in carbon under higher temperatures. However these results may not be inconsistent as they consider different metrics in differer [70] Cornell University 8/19/2015 10:53 AM

Deleted: Cornell University 8/19/2015 10:53 AM Deleted: between Cornell University 8/19/2015 10:53 AM Deleted: 14b Cornell University 8/19/2015 10:53 AM Deleted: 14c vs. Figure 12c). of LAI ultimately rest on the ability of models to project future precipitation, Yet, in
many regions the projected changes in precipitation are not large enough to be
statistically significantly outside natural variability (e.g. Tebaldi et al, 2011) and
there are discrepancies between climate model and statistical model predictions
(e.g. Funk et al., 2014 vs. Tebaldi et al., 2011). In addition, increasing temperatures
are likely to stress systems, even if there is additional rainfall (e.g. Lobell et al.,
2011), expanding the regions at risk to increased drought (Figure 6).

| 12 | accurately simulating the mean I | AI spatial distribution? 2) are the models accurately simula | ting the seasonal cycle in LAI? 3) |
| 13 | are the models correctly simulat | ing the processes driving interannual variability in the curr | ent climate? And finally based on |
| 14 | this analysis, 4) can we reduce t | he uncertainty in future projections of LAI by using each mo | odel's skill in the current climate? |
| 15 | Overall, models are able to captu | re some of the main characteristics of the LAI mean and sea | sonal cycle, but all of the models |
| 16 | can be improved in one or more | regions. Comparison of the modeled and observed interann | ual variability in the current |
| 17 18 | climate suggested that in high la | titudes the models may overpredict | |
| 19 | Page 2: [4] Deleted | Cornell University | 8/19/15 10:53 AM |

| 1 | based on warming temperature, while in the tropics the models may overpredict the negative impacts | of warming |
|----------|---|---------------------|
| 2 | temperature on LAI. We expect, however, larger uncertainties in observational estimates of interannual LAI co | ompared to |
| 3 | estimates of seasonal or mean LAI. | |
| 4 | Future projections of LAI by the ESMs are largely optimistic, with only limited regions seeing reductions in LA | I. Future |
| 5 | projections of LAI in the models are quite different, and are sensitive to climate model projections of precipita | tion. They |
| 6 | | |
| 7 | Page 2: [5] Deleted Cornell University | 8/19/15 10:53 AM |
| 8 | strongly depend on the amount of carbon dioxide fertilization in high latitudes. Based on comparisons betwee | en model |
| 9 10 | simulated LAI and observed LAI in the current climate, we can reduce the spread in model future projections, | especially in |
| 11 | Page 2: [6] Deleted Cornell University A | 8/19/15 10:53 AM |
| 12 13 | , by taking into account model skill. In the tropics the models which perform the best in the current climate | |
| 14 | Page 2: [7] Deleted Cornell University | 8/19/15 10:53 AM |
| 15 | average of all models. These top performing models also project an increase in the frequency of drought in sor | me regions of the |
| 16 17 | tropics, with droughts being defined as minus one standardized deviation events. | |
| 18 | Page 5: [8] Deleted Cornell University 8 | 8/19/15 10:53 AM |
| 19 | have been used to identify trends in NDVI and LAI (Forkel et al., 2013; Jong et al., 2013; Mao et al., 2013 | 3; Vrieling et al., |
| 20 | 2013). While satellite derived LAI estimates are known to have systematic and random errors, they have been | usefully |

| 1 | employed to evaluate the relative | importance of different climate factors (e.g. temperature, precipitat | ion) for vegetation |
|----|--------------------------------------|---|----------------------------|
| 2 | productivity (Zeng et al., 2013). W | /e expand on previous studies that evaluated simulated LAI (e.g. An | av et al. 2013) by looking |
| 3 | at LAI means and variability acros | s all latitudes, and considering what climate factors impact interanr | ual variability. |
| 4 | There are several potential drivers | s of LAI changes in the future, such as temperature, precipitation, as | well as carbon dioxide |
| 5 | fertilization, which can impact futu | ıre | |
| 6 | | | |
| 7 | Page 5: [9] Deleted | Cornell University | 8/19/15 10:53 AM |
| 8 | . Based on the interannual variabi | lity of LAI and climate drivers in the current climate, we consider w | hether the models can |
| 9 | reproduce the observed relationsh | nips, suggesting they have the correct sensitivity to such important o | drivers of LAI as |
| 10 | temperature or precipitation (e.g. | Fung et al., 2005; Lobell et al., 2011; Zeng et al., 2013). The main qu | uestions we seek to |
| 11 | answer in this paper are 1) are the | e models accurately simulating the mean LAI spatial distribution? 2) |) are the models |
| 12 | accurately simulating the seasonal | cycle in LAI? 3) are the models correctly simulating the processes of | driving interannual |
| 13 | variability in the current climate? | And finally based on this analysis, 4) can we reduce the uncertainty | <i>i</i> in future |
| 14 | | | |
| 15 | Page 5: [10] Deleted | Cornell University | 8/19/15 10:53 AM |
| 16 | of LAI by using each model's skill | in the current climate? I (e.g. | |
| 17 | | | |
| 18 | Page 5: [11] Deleted | Cornell University | 8/19/15 10:53 AM |

| 1 | 2010)? To this end, we develop several metrics to evaluate the models' ability (similar to that done for other climate |
|---|--|
|---|--|

- 2 variables, e.g. Taylor, 2001), some of which could be used in future model intercomparisons (e.g. Luo et al., 2012; Randerson
- 3 et al., 2009).
- 4 In this paper we present in our methods

| 5 | | | |

| 18 | | | |

Model variables analyzed included monthly-mean precipitation, surface temperature, and LAI. Only models which had
 data for all these variables, for historical and RCP8.5 scenarios, were included in this study.

3

Page 8: [15] Moved to page 6 (Move #8) 4 **Cornell University** 8/19/15 10:53 AM Some models submitted multiple versions, at different resolutions or with slightly different physics (Table 1). Even though 5 some of the models are closely related (e.g. CESM1-BGC and NorESM-ME), we include different configurations of the same 6 model. 7 8 Page 8: [16] Deleted 9 8/19/15 10:53 AM **Cornell University** LAI's relationship with climate variables 10 11 12 Page 8: [17] Deleted **Cornell University** 8/19/15 10:53 AM 13 In order to assess the ability of the earth system models to simulate the temperature and precipitation dependence of LAI in the future, we use current relationships in the observations of LAI and climate. We want to evaluate whether the 14 15 models have the correct temperature and precipitation impacts on vegetation. To do so, we develop several metrics. 16 For the models and the observations, we show results based on annual averages. We also considered a more complicated time period, where the LAI and temperature are based on growing seasons. The growing season is defined as the 17 18 monthly maximum LAI and its two adjacent months. Because previous studies (e.g. Zeng et al., 2013) have shown that precipitation shows the highest correlation at 1-3 months ahead of vegetation, we use average precipitation for the month of 19

| 1 | the maximum LAI and the three previous r | months. This implies that pre-maximum LAI precipitation | is most important for soil |
|--|--|--|---|
| 2 | moisture during the growing season (Funk | k and Budde, 2009). Zeng et al. 2013 showed that tempera | ature correlations are |
| 3 | highest with vegetation during the month | of maximum LAI, and thus temperature during the growing | ng season is used. Results |
| 4 | obtained using the growing season were q | uantitatively different from using an annual average, but | qualitatively similar, and |
| 5 | with similarly strong correlations. Thus fo | or simplicity we present only results using the annual time | e period metrics in this |
| 6 | paper. | | |

At each grid box, a correlation betwee e.g. the trend with time) against leaf area index are obtained mulate exactly the same climate as observed, we cannot e | 8/19/15 10:53 AM 8/19/15 10:53 AM o leaf area index in the en the annual mean of ed for each model and xpect the models to |

| 1 | similar between the model and observations. Thus, we calculate the temporal correlation between LAI and temperature, LAI |
|----|---|
| 2 | and precipitation, and LAI and time (e.g. incrementing the year, to see if there is a trend in time), at every grid point, and |
| 3 | calculate the spatial average of each correlation across the different regions (Table 2: LAI vs. T: Avg. Corr. for example). |
| 4 | We also perform a comparison of LAI simulated in a fully coupled model simulation to LAI simulated by a land model |
| 5 | driven by observationally derived datasets (called CLM-obs) (e.g. Qian et al., 2006), but extended using CRU data through 2010 |
| 6 | (Harris et al., 2013) for the Community Land Model (Lawrence et al., 2012; Lindsay et al., 2014). For this model, substantial |
| 7 | computer software development has occurred so that the same model can be similarly driven by observation-based |
| 8 | meteorology ("offline) or the simulated meteorology ("online") (Oleson et al., 2013). The reason for including this simulation |
| 9 | is to test the sensitivity of the results to different driving meteorology. If we compare the same model driven by different |
| 10 | meteorological data, we can isolate metrics that can identify model traits, from those that are dependent on meteorology, or |
| 11 | simply are not strong enough to be used as metrics. Of course this analysis is dependent on the model and datasets used, but |
| 12 | can be used as a sensitivity study to suggest how important meteorological factors are in the analysis. |
| 13 | Other metrics were also considered for this paper, including the overlap in the probability density functions (e.g. |
| 14 | Maxino et al., 2008) and root mean squared differences, but these did not provide additional information that would justify the |
| 15 | additional complexity in the paper. |
| 16 | |

| 1 | Page 21: [20] Deleted | Cornell University | 8/19/15 10:53 AM |
|----|--|--|-----------------------------|
| 2 | We evaluate the mean change in the fut | ure using the RCP8.5 scenarios for temperature, precipitation | , and LAI (e.g. Tables 3 |
| 3 | and 4) using the models listed in Table 2 | 1. RCP8.5 is the most extreme scenario in the CMIP5 archive. | We use it to identify |
| 4 | regions that are most at risk in the futur | re. Areas with mean changes in LAI, precipitation, and temper | rature that are larger than |
| 5 | the historical variability indicate statisti | ically changes to climate and vegetation from current climate. | To highlight where |
| 6 | models predict these areas will be, mean | n changes over 20 year time periods are divided by the standa | ard deviation over the |
| 7 | current climate (1981-2000) and shown | n in terms of standard deviation units (e.g. Mahlstein et al. 20 | 12; Tebaldi et al. 2011). |
| 8 | The spatial and temporal scale we use to | o define these changes can be important for whether these sig | nals are statistically |
| 9 | significant (Lombardozzi et al., 2014) ar | nd we calculate this using a 20-year time scale at the grid leve | 1. |
| 10 | In addition, there could be chang | es in LAI variability, which may also be important for underst | anding the impact of |
| 11 | climate change. For many regions we a | re concerned about the incidence of time periods with low pre | ecipitation and/or high |
| 12 | temperatures causing low vegetative pr | oductivity, which we will refer to here as drought. In terms o | f drought, the length and |
| 13 | frequency matter, so the percent of the | time during which the variable is in drought is also calculated | . We define drought as |
| 14 | time periods where LAI is one standard | deviation (evaluated during the current climate) below that o | of the mean during the |
| 15 | current climate. By definition, if the var | riables have a Gaussian distribution, each gridbox would be in | 'drought' for 1/6 (16%) |

1 of the time. Thus we seek to estimate the fraction of the time in the future that this condition exists, and specifically whether it

- 2 increases in the future.
- 3
- 4 **3.0**
- 5

| 6 | Page 21: [21] Deleted | Cornell University | 8/19/15 10:53 AM |
|----|--|--|--------------------------------|
| 7 | Our goal in this section is to explore the | e value of a new 30 year satellite LAI record for evaluating | g LAI simulations in the |
| 8 | current generation of CMIP5 models. (| Anav et al. 2013) evaluated the LAI seasonal cycle and int | terannual variability for |
| 9 | current climate high latitude Northern | Hemisphere simulations. Here we look across all regions | s and also look at the |
| 10 | temperature and precipitation as poter | ntial drivers of interannual variability. | |
| 11 | 3.1 Climatological comparison | | |
| 12 | The observed mean LAI has the largest | values of leaf area index in the tropics (Figure 1a). The la | argest seasonal cycle tends to |
| 13 | be in mid-latitude regions, although the | ere is still a signal in some parts of the tropics (Figure 1b) | . The interannual variability |
| 14 | tends to be much smaller than the seas | ional cycle, and is equally large in tropics, mid-latitudes a | nd high latitudes (Figure 1c). |
| 15 | One should note that there are many p | ossible errors in the observational datasets, although the | latest versions used here tend |

16 to have smaller biases than previous versions (

| 2 | Page 21: [22] Deleted | Cornell University | 8/19/15 10:53 AM |
|----|---------------------------------------|--|------------------------------------|
| 3 | 2013). In this study, we compare m | nodel simulations against the satellite data, recognizing that | at these data are not perfect, and |
| 4 | thus our conclusions are sensitive to | o potential biases in the observational data. | |
| 5 | The | | |
| 6 | | | |
| 7 | Page 22: [23] Deleted | Cornell University | 8/19/15 10:53 AM |
| 8 | overpredict the strength of the seas | onal cycle differ. Several models underpredict the seasona | ll cycle at high-latitudes (e.g. |
| 9 | CanESM2, CESM1-BGC, GFDL-ESM2 | G, GFDL-ESM2M, INMCM4, IPSL-CM5A-LR, IPSL-CM5A-MF | R, IPSL-CM5B-LR) (Figure 2b, 2h, |
| 10 | 2k; Table 4; Anav et al. 2013). The r | nagnitude and direction of bias in model projections also v | vary by region. For example, one |
| 11 | set of models overpredicts the stren | gth of the seasonal cycle in the tropics and mid-latitudes, | but underpredicts in the high- |
| 12 | latitudes (e.g. bcc-csm1, bcc-csm1_1 | .), while one set of models overpredicts the seasonal cycle | at mid latitudes, but |
| 13 | underpredicts in the tropics (e.g. MI | ROC models). Another set of models underpredict the seas | sonal cycle across all latitudes, |
| 14 | but especially the tropics and high-l | atitudes (e.g. HadGEM2 models). The spatially averaged o | correlations between the |
| 15 | seasonal cycle in the observations a | nd models show a range of between 0.2 to 0.58 (Table 4), | suggesting the need for |
| 16 | substantial improvement in the time | ing of the seasonal cycle. Of course, there is not a strong se | easonal cycle in the tropics, |
| 17 | where the lowest correlations tend | to occur (Table 4a). A smaller seasonal signal in this regio | on could lead to larger relative |

1 errors in the observational estimates, and the smaller seasonal signal could be harder for models to simulate accurately. In

2 mid-latitudes, where the seasonal cycle is likely to be more robust, the correlation coefficient averages above 0.5 for most

3 models, except for the GFDL models and the INMCM4 (Table 4b).

4

| 5 | Page 23: [24] Deleted | Cornell University | 8/19/15 10:53 AM |
|----------|--------------------------------------|---|-----------------------------------|
| 6 | within the earth system model (Figu | are 2 and Table 3 and 4: CLMobs vs. CESM row of Table 2). T | his suggests that these metrics |
| 7 | are more model dependent than me | teorology dependent. Of course, with another model we mig | ht obtain a different result, but |
| 8 | this result suggests that these mode | el tests are | |

18 climate variables on the interannual time scale. Our goal is to assess whether the models can simulate the observed

19 relationships between interannual variation in

| 1 | Page 23: [28] Deleted | Cornell University | 8/19/15 10:53 AM |
|----|--|--|------------------------------|
| 2 | precipitation and the interannual variability in LA | AI. In addition, we also consider whether there is | |
| 3 | | | |
| 4 | Page 23: [29] Deleted | Cornell University | 8/19/15 10:53 AM |
| 5 | the LAI (thus a correlation between advancing tin | ne and the LAI in the observations and the model). | The observations suggest |
| 6 | statistically significant relationships between inte | erannual variability in | |
| 7 | | | |
| 8 | Page 23: [30] Deleted | Cornell University | 8/19/15 10:53 AM |
| 9 | and temperature, precipitation, and time trends (| Figure 3). | |
| 10 | | | |
| 11 | Page 23: [31] Deleted | Cornell University | 8/19/15 10:53 AM |
| 12 | Precipitation patterns tend to show positive corr | elations in many regions (Figure 3b), but with som | e high latitude regions |
| 13 | exhibit a negative correlation of precipitation with | h LAI. These relationships highlight the regional na | ature of sensitivity to |
| 14 | temperature or precipitation, as seen in previous | studies (e.g. Anav et al. 2013; Ichii et al. 2002; War | ng et al., 2013; Zeng et al. |
| 15 | 2013). High latitude regions, furthermore, may de | epend on snowfall, which will be poorly captured b | y our precipitation |
| 16 | compositing procedure | | |
| 17 | | | |
| 18 | Page 24: [32] Deleted | Cornell University | 8/19/15 10:53 AM |
| 19 | | | |

| 1 | Model simulations can capture many of these relationships (e.g. Figure 4 vs. Figure 3), but with varying strengths |
|----|--|
| 2 | (Table 3; Figure 5). Because the coupled models are not intended to predict specific events or decadal variability, we want to |
| 3 | evaluate the broad pattern of these relationships, instead of specific details. Thus, we consider the spatial mean of the |
| 4 | temporal correlation between LAI and climate variables in the observations and model (as described in Section 2.3; Table 3 |
| 5 | and 4; Figure 5). This tests, for example, whether the models capture the mainly positive correlation between LAI and |
| 6 | temperature in high latitudes and mixed but more negative correlation in the tropics (Figure 3a; Figure 4a, Figure 5). |
| 7 | Notice that for one land model (the CLM), simulated interactively within an earth system model (CESM-BGC) (Figure |
| 8 | 4a) presents more similar results of the LAI-temperature correlation to the CLM driven by observed-based datasets (CLM-obs) |
| 9 | (Figure 4b) than to either the observations (Figure 3a), or other models (Figure 4d or 4e). Thus, LAI correlations with |
| 10 | temperature indicate a metric that appears to be intrinsic to the CLM model. Both the CLM and CLM-obs simulations (Figure |
| 11 | 4a,b) exhibited stronger negative LAI-temperature correlations over the tropics than seen in the observations (Fig. 3a). In |
| 12 | general, almost all of the models exhibited a much stronger negative correlation between temperature and LAI in the tropics |
| 13 | (Table 4a; Figure 5) than that observed. |
| 14 | The relationship between CESM and CESM-obs LAI-precipitation relationships (e.g. Figure 4c and 4d compared to Figure 4a |

and 4b) are weaker. In fact, LAI-precipitation relationships do not appear to be more similar when the CLM within the CESM is

| 1 | compared against the CLM driven by observed | d-meteorology (Table 3 and 4), suggesting that LAI- | precipitation relationships |
|---------------------------------------|--|--|---|
| 2 | 2 are very sensitive to the meteorology used, an | nd not a good metric to be tested in a coupled earth | system environment. This |
| 3 | could be due to the fact that precipitation has | a weaker relationship with LAI, except in an occurr | ence of rare but strong |
| 4 | drought (e.g. Funk and Brown, 2006). Or this | could be due to more complicated time lags that nee | ed to be considered or |
| 5 | because random chance becomes too importa | ant. Growth in many tropical regions may be radiati | on limited, rather than water |
| 6 | 5 limited. | | |

| 3 | Page 26: [39] Deleted | Cornell University | 8/19/15 10:53 AM |
| 4 | An example set of model time seri | es of temperature, precipitation, net primary production and | l leaf area index from 1900- |
| 5 | 2100 shows that, similar to previo | ous modeling studies (Doherty et al. 2010; | |
| 6 | | | |
| 7 | Page 26: [40] Deleted | Cornell University | 8/19/15 10:53 AM |
| 8 | 2007), there is a mean increase in | precipitation, as well as leaf area index in this region (Figure | e 7). However, one model (IPSL- |
| 9 | CMA-LR) shows an increase LAI va | ariability (Figure 7a), which could have large negative impac | ts to the local population |
| 10 | despite an increased mean LAI. As | this simple example suggests, for studies on the impact of cl | limate change, we should look |
| 11 | not only at the mean change in lea | f area index, but also look at changes in the variability of leaf | f area index, in order to identify |
| 12 | regions which may be at risk for fa | amine in the future. | |
| 13 | The projections for future l | LAI are quite variable across different models for this region | (Figure 8), although generally |
| | | | |

- 14 quite optimistic in most of the CMIP5 models. For example, one model (BNU-ESM) predicts very large increases in LAI (>4;
- 15 Figure 8a), while another (MPI-ESM) predicts modest increases and decreases (<0.5; Figure 8b). Normalizing

| 8 | climate and statistically sig | nificant (e.g. Tebaldi et al., 2011), shows similar patterns. Notice tha | t if the standard deviation in |
| 9 | the current climate is zero (| [i.e. there is not interannual variability reported at this grid box), the | e normalized difference is not |
| 10 | finite, and is removed from | further analysis. Some models are quite optimistic in East Africa, where | hile others are less so (Figure |
| 11 12 | 8c vs. | | |
| 13 | Page 26: [45] Formatted | Cornell University | 8/19/15 10:53 AM |
| 14 | Font:Bold | | |
| 16 | Page 26: [46] Deleted | Cornell University | 8/19/15 10:53 AM |
| 17 | Usually we consider | the multi-model mean for future projections (e.g. Meehl et al., 2007) |). Model mean climate |
| 18 | projections for the next cen | tury suggest statistically significant increases in LAI (the mean chan | ge divided by current |
| 19 | variability) over most of Ea | st Africa (Figure 9a, 9c and 9e). But some regions see a reduction in | mean LAI after the mid-century. |
| 20 | If we consider also the poss | ibility of an increased mean, and also increased variability, which ma | ay indicate more frequent |
| 21 | drought, we see that broad | areas of East Africa are at a higher risk for drought by 2090 (Figure 4 | 9e), despite a higher mean LAI. |

Here we define drought as the percent of time LAI is one or more standard deviations below the mean (as defined in the 1 current climate), and thus any non-gray colored area indicates a higher drought risk than in the current climate (Figure 9b; 9d; 2 and 9f). While the areas with increased drought tend to be in regions with reductions in mean LAI, or smaller increases in LAI, 3 the projections for increased drought show large regions at risk and thus maybe a more conservative metric for future 4 vulnerability studies. 5 To consider the question of whether models project an increased risk of drought in East Africa in the future, one must 6 also keep in mind that there are larger uncertainties in projections at smaller scales (e.g. Hawkins and Sutton, 2009), and thus 7 one should not believe that in Kenva, for example, there will be an increase in LAI, while neighboring countries will necessarily 8 9 see a decrease. The ability of the models to resolve and project at such small scales is not strong enough (e.g. Hawkins; Sutton 10 2009). Broader scale patterns considered in the next section are likely to be more robust. In addition, the projection of 11 precipitation estimated in climate models for this region, which tend to be optimistic, is quite different than statistical studies which suggest less precipitation in a warming climate (e.g. Jury and Funk, 2013). Many of the observed drying trends in this 12 13 region are linked to the sea surface temperature gradient between the equatorial western and central Pacific (Funk et al., 14 2014). While this gradient has strengthened, causing an intensification of the Walker circulation and drying, the future state of 15 this gradient is uncertain.

2 4.2 Global projections

At the global level, there is also variability in the projections of future LAI changes. Some models project large increases while 3 other project more modest increases (e.g. Figure 10a and 10b; notice the different scale). After normalizing by the standard 4 deviation to highlight the results that are statistically significant (Figure 10c and 10d), we still see large variations in the 5 projections, especially in the tropics. 6 The 21st century projections of mean model LAI (normalized by the standard deviation in each model) suggest a 7 statistically significant increase in leaf area index over much of the globe, especially high latitudes (Figure 11). Some tropical 8 regions are seen to be at risk for reductions in mean LAI, such as in Central America and the Amazon basin. These regions are 9 10 also at risk of more frequent drought, as identified by the percent of the time their LAI is below one standard deviation of the 11 current mean (Figure 11b,d f). More frequent drought is also projected for large areas of the tropics and subtropics where

12 projected increases to mean LAI are small in magnitude or negligible (Figure 11a vs b, for example).

13 Models vary in how much change they project in the future (Figure 12). The model projections tend to have larger

14 increases than decreases in absolute magnitude of the LAI (Figure 12), and some models project very large increases, while

15 there are only very small decreases predicted in a small number of cases.

| 2 | 4 | | |
|----|--|---|--|
| 3 | | | |
| 4 | Page 26: [47] Moved to page 17 (Move #12) | Cornell University | 8/19/15 10:53 AM |
| 5 | .3 Drivers of LAI projections | | |
| 6 | Next we consider what drives the differences in r | nodel projections for LAI, using the exa | mple of RCP8.5 at 2080-2100. |
| 7 | | | |
| 8 | Page 26: [48] Deleted | Cornell University | 8/19/15 10:53 AM |
| 9 | By correlating at each grid box, across the | e models, the temperature and LAI proje | ections, we can look for relationships |
| 10 | between model projections of temperature and L | AI, which may be causal (Figure 13a). | There are strong positive correlations |
| 11 | between model simulated changes in temperatur | e and LAI in some regions, especially th | e northern high latitudes, suggesting |
| 12 | that models with a projected larger warming in t | he high latitudes also simulate larger in | creases in LAI. On the other hand, |
| 13 | there are strong negative correlations in the trop | vics, for example the Amazon (Figure 13 | a), suggesting that models that |
| 14 | simulate higher tropical temperature changes ter | nd to have lower LAI projections in the f | future. Notice that while higher |
| 15 | temperatures may drive higher LAI, higher LAIs | may also be driving higher temperature | s because of the importance of LAI in |
| 16 | changing surface energy fluxes (e.g. Lawrence an | d Slingo, 2004). | |

| 1 | The projected changes in precipitation are | e strongly correlated with projected c | hanges in LAI, when we correlate across |
|----|--|---|--|
| 2 | 2 models (Figure 14a), suggesting that changes in | precipitation across the models drive | much of the difference between models |
| 3 | in many regions. In addition, if we look spatially | at where the lower LAIs occur, it is w | here the precipitation has decreased. |
| 4 | If a region has a model mean lower precipitation | in the in the future (Figure 13c), it als | so has lower LAI predicted by the model |
| 5 | mean (Figure 11e). | | |
| 6 | Another important potential contributor to the f | uture projections of LAI is the effectiv | eness of the carbon fertilization in the |
| 7 | models (e.g. Arora et al. 2013). | | |
| 8 | 3 | | |
| 9 | Page 26: [49] Moved to page 19 (Move #14) | Cornell University | 8/19/15 10:53 AM |
| 10 | Using the carbon dioxide fertilization factor (β -l | and) from the Arora et al. (2013) stud | ly we use a rank correlation to explore |
| 11 | the importance of the carbon dioxide fertilization | n strength for predicting future | |
| 12 | | | |
| 13 | Page 26: [50] Moved to page 19 (Move #15) | Cornell University | 8/19/15 10:53 AM |
| 14 | We would expect models that respond more str | ongly with increased carbon uptake u | nder higher CO ₂ conditions (i.e. |
| 15 | 5 | | |
| 16 | Page 26: [51] Formatted | Cornell University | 8/19/15 10:53 AM |
| 17 | Subscript | | |
| 19 | Page 26: [52] Deleted | Cornell University | 8/19/15 10:53 AM |

1 larger β -land) to have greater LAI in the future. Globally the correlation is 0.34, suggesting that some of the differences in

2 future LAI projections across models is due to differences in the model simulation of CO₂ fertilization. The value is -0.36, 0.26

3 and 0.58, for tropical, mid-latitude and high latitude, regions, respectively.

4

| 5 | Page 26: [53] Moved to page 19 (Move #16) | Cornell University | 8/19/15 10:53 AM |
|----|---|--|-----------------------------------|
| 6 | Thus for high latitudes, especially, the pro- | ojections of LAI appear to be dependent on the wa | y the models' simulate the carbon |
| 7 | dioxide fertilization in the different model | s. This could also be, however, an artifact that the | two models with the lowest |
| 8 | carbon dioxide effect (CESM-BGC and NOF | R-ESM) use the same land carbon model | |
| 9 | | | |
| 10 | Page 26: [54] Deleted | Cornell University | 8/19/15 10:53 AM |

11 , which predicts low values of LAI in high latitudes for present day and does not tend to increase LAI much in the future

12 (Thornton et al., 2009). These models also have low carbon dioxide fertilization effects, because of their nitrogen colimitation,

13 which could be driving the correlation between model projections of LAI and carbon dioxide fertilization in the high latitudes.

14 It is interesting that in the tropics the carbon dioxide fertilization is negatively correlated to future LAI changes.

15

16 Page 26: [55] Moved to page 20 (Move #17)

Cornell University

8/19/15 10:53 AM

1 Again, this could be an artifact of having only two related low carbon fertilization models, as these models see a strong

2 increase in nitrogen mineralization in the tropics in a warming climate, which allows an increase in productivity in the future

3 tropics (Thornton et al., 2009).

4

| 5 | Page 26: [56] Deleted | Cornell University | 8/19/15 10:53 AM |
|----|--|---|--------------------------------------|
| 6 | In other words, the strong negative | e correlation in the tropics between LAI projections a | nd CO_2 fertilization could be due |
| 7 | to the smaller temperature impact on carb | bon cycle in the N-limited models (the β -land and γ -la | and (climate impact on carbon |
| 8 | cycle) are negatively correlated in Table 2 | ? of Arora et al., 2013). | |
| 9 | Finally, the disconnect between carbon di | oxide fertilization effect and future LAI in the mid-lat | titudes and tropics could also be |
| 10 | due to the way that carbon is allocated am | nong different biomass pools in models. For example, | in the CLM, the land model for |
| 11 | the CESM-BGC, CO_2 fertilization causes a la | arger increase to wood allocation (62%) than to leaf | allocation (21%) in the |
| 12 | Southeastern US (Lombardozzi, personal | communication, 2015). | |
| 13 | | | |
| 14 | Page 26: [57] Moved to page 19 (Move #13) | Cornell University | 8/19/15 10:53 AM |
| 15 | Thus, the issue of how LAI responds in dif | ferent models is interesting and should be considere | d in future studies. |
| 16 | | | |
| 17 | Page 26: [58] Deleted | Cornell University | 8/19/15 10:53 AM |
| 18 | | | |
| | | | |

| 1 | 4.3 | | |
|----------|---|---|--|
| 2 | | | |
| 3 | Page 26: [59] Moved to page 20 (Move #18) | Cornell University | 8/19/15 10:53 AM |
| 4 | Reducing spread in the future projections | | |
| 5 6 | There are large differences between th | e different models' projections of future | LAI (e.g. |
| 7 | Page 26: [60] Deleted | Cornell University | 8/19/15 10:53 AM |
| 8 | Figure 12; Figure 14c). Previous studies have | tried to reduce the uncertainty in future | projections by looking for relationships |
| 9 | between model metrics and future projection | s, and then choosing the models which be | est match the observations in the |
| 10 | current climate (e.g. | | |
| 11 | | | |
| 12 | Page 26: [61] Moved to page 20 (Move #19) | Cornell University | 8/19/15 10:53 AM |
| 13 | Cox et al., 2013;Hoffman et al., 2014) or by su | bsampling models for different regions b | y their performance (e.g. Steinacher et |
| 14 15 | al., 2010). In this section we use both approa | ches to try to reduce the spread in | |
| 16 | Page 26: [62] Deleted | Cornell University | 8/19/15 10:53 AM |
| 17 | projections at the end of the 21 st century (208 | 31-2100). In essence, we are looking for a | a correspondence between current |
| 18 | model performance and the future projection | , in order to reduce the uncertainty in the | e future projections. In many cases in |
| 19 | climate modeling and projections, there is no | correlation between current climate skill | l and projections (e.g. |
| 20 | | | |

| 1 | Page 26: [63] Moved to page 21 (Move #20) | Cornell University | 8/19/15 10:53 AM |
|----|--|---|--------------------|
| 2 | Cook and Vizy, 2006), however in some limited cases | there is a correlation between metric score and a proje | ection, and one is |
| 3 | able to constrain future projections (e.g. Cox et al., 201 | 13; Steinacher et al., 2010). | |

1 Table 3: Evaluation of LAI over globe. Metrics are described in text and Table 2, models in Table 1. The CESM vs. CLM column

- 2 indicates the value of the comparison between the CESM1-BGC and the CLM-obs simulations (which use the same land model,
- 3 but different meteorology). The Corr Δ LAI row indicates the correlation coefficient across models between the model value of
- 4 this metric (this column) against the change in LAI in 2080-2100 (last column).

Table 4c. High-latitude LAI evaluation and projections. As in Table 3, but for high-latitude region (> 50°).

Table 5

Page 40: [74] DeletedCornell University8/19/1510:53 AM2: Probability density function (pdf) of observed (thick black line) and modeled LAIfor mean (first column), seasonal cycle standard deviation (middle column) andinterannual variability standard deviation (right column) for global (a, b, c), tropical(<30°)</td>(d, e, f), mid-latitude (between 30° and 50°)(g, h, i) and high-latitudes(>50°)(j, k, l), respectively. Probability density functions are smoothed using anEpanechnikov smoothing kernel. Models are show as colored lines, as indicated onlegend in figure. CLM-obs (driven by observational-derived dataset, with the sameland carbon model as CESM-BGC) is shown as a dotted line).

Figure 3: Rank correlation between observationally-derived interannual variability in LAI and temperature (a) and precipitation (b), and year(c). Correlations above an absolute value of 0.36 are significant at the 95% and are shown in darker colors. Observations are derived from satellite retrievals (Zhu et al. 2013) for LAI and gridded datsasets GHCN (Fan; Dool 2008) for temperature and GCPC (Adler et al. 2003) for precipitation

Figure 4: Rank correlation between model derived LAI and temperature (a and b) and precipitation (c and d) for the CESM-BGC (a and c) and for the CLM-obs (b and d). Both models have the same land model, but the difference is that the CESM-BGC meteorology is from the coupled climate model, while the CLM-obs is driven by datasets constrained by observations (Harris et al. 2013; Qian et al. 2006). The rank correlation between model derived LAI and precipitation are shown for the IPSL-CM5A-LR and INM-CM4 models are shown in e and f, respectively.

Figure 5. Probability density function (pdf) of rank correlations for the rank correlation between temperature (first column), precipitation (middle column) and date (right column) for global (a, b, c), tropical (<30°) (d, e, f), mid-latitude (between 30° and 50°) (g, h, i) and high-latitudes (>50°) (j, k, l), respectively. Probability density functions are smoothed using an Epanechnikov smoothing kernel. Models are show as colored lines, as indicated on legend in figure. CLM-obs (driven by observational-derived dataset, with the same land carbon model as CESM-BGC) is shown as a dotted line

|-------------------------------|--|---------------------------|--|--|--|--|--|--|--|--|
| 8: East African differences i | 8: East African differences in mean LAI between future climate (2081-2100) and | | | | | | | | | |
| aurrent dimete (1001 2000 |)) from two different models. D | NULESM (a) and MDLESM | | | | | | | | |
| current chinate (1981-2000 |)) from two different models: B | NU-ESM (a) and MPI-ESM | | | | | | | | |
| (b) (notice the different sca | le). Difference in mean LAI (20 | 81-2100 minus 1981- | | | | | | | | |
| 2000) divided by the standa | ard deviation in LAI (1981-200 | 0) for BNU-ESM (c) and | | | | | | | | |
| MPI-ESM (d). Regions with | a zero standard deviation are le | eft blank. Regions with | | | | | | | | |
| absolute value > 1 are more | than one standard deviation a | way from current climate. | | | | | | | | |

Figure 9: Mean of all models for the annual mean change in LAI over time relative to current period (1981-2000) focused on East Africa, normalized by each model's current (1981-2000) standard deviation at each grid point, for 2011-2030 (a), 2041-2060 (c) and 2081-2100 (e). Drought frequencies based on the modeled

mean percent of time that LAI is more than one standard deviation below the current mean LAI for 2011-2030 (b), 2041-2060 (d) and 2081-2100 (f), where the current mean and standard deviation are defined for each grid box for 1981-2000.

 Page 41: [76] Moved to page 40 (Move #29)Cornell University
 8/19/15 10:53 AM

For the current climate, the percentage of time below one standard deviation will be 16%, which is colored in grey, so all colors represent an increase in drought.

Page 41: [77] DeletedCornell University8/19/1510:53 AMFigure 10: Global differences in mean LAI between future climate (2081-2100) and
current climate (1981-2000) from two different models: BNU-ESM (a) and MPI-ESM(b) (notice the different scale). Difference in mean LAI (2081-2100 minus 1981-
2000) divided by the standard deviation in LAI (1981-2000) for BNU-ESM (c) and
MPI-ESM (d). Regions with a zero standard deviation are left blank. Regions with
absolute value > 1 are more than one standard deviation away from current climate.
(as in Figure 7, but global).

Figure 11: Mean of all models for the annual mean change in LAI over time relative to current (1981-2000) (same as Figure 7, but for globe), normalized by each model's current (1981-2000) standard deviation at each grid point, for 2011-2030 (a), 2041-2060 (c) and 2081-2100 (e). Indication of drought is the model mean percent of time that LAI is more than one standard deviation below the current mean LAI and is shown for 2011-2030 (b), 2041-2060 (d) and 2081-2100 (f), where the current mean and standard deviation are defined for each grid box for 1981-2000. For the current climate, the percentage of time below one standard deviation will be 16%, which is colored in grey, so all colors represent an increase in drought.
