Interactive comment on “The Half-order Energy Balance Equation, Part 2: The inhomogeneous HEBE and 2D energy balance models”

FOR THE EQUATIONS SEE THE SUPPLEMENT

Anonymous Referee #1 Received and published: 10 July 2020

General comments: I think this is a notable (two-part) paper. Its key message, that the heat flux at the earth's surface is a derivative of order half of the temperature, and that this modifies the simplest EBMs in an important way is both significant in itself, and

C1

provides a foundation for the author's concurrent work on fractional stochastic energy balance models.

Au: Thank you for the enthusiastic review!

I have only one gripe that needs attention. It relates to earlier work which needs to be more fully described and integrated into the manuscript. When this is done so it will actually reinforce the author's message, I think.

Au: The Oldham references are quite useful, thanks! I respond in more detail below.

Specific comment: Earlier work on half-order derivatives in heat transfer The list of references on fractional calculus seems to me to be comprehensive in general, but to be missing a key reference. Podlubny [1999] notes in his preface that:... from the viewpoint of applications in physics, chemistry and engineering it was undoubtedly the book written by K. B. Oldham and J. Spanier [i.e. "The Fractional Calculus", Academic Press, 1974; now in a Dover Edition] which played an outstanding role in the development of the subject which can be called applied fractional calculus. Moreover, it was the first book which was entirely devoted to a systematic presentation of the ideas, methods, and applications of the fractional calculus.

Referring back to this book suggests to me that to say, as the manuscript presently does, that "... half-order derivatives have occasionally [sic] been used in the context of the heat equation, (at least since [Babenko, 1986]) "substantially underestimates the extent to which half order derivatives have already been studied in the heat equation context. Oldham and Spanier devote their chapter 11 to applications of what they call the semi differential operator, i.e. the fractional derivative of half order, to diffusion problems including heat transfer.

The book built on their own papers, particularly Oldham KB, Spanier J (1972) A general solution of the diffusion equation for semi infinite geometries, J Math Anal Appl 39:665–669 and Oldham KB (1973) Diffusive transport to planar, cylindrical and spherical

C2

electrodes, *J Electroanal Chem Interfacial Electrochem*, 41:351–358. They give the diffusion equation as:

and then note that in three special, semi-infinite, cases this can be simplified so that Laplacian depends only on the radial co-ordinate  $r$  and  $t$ . In the planar case they give:

They take the system is initially in equilibrium  $F(r,t) = F_0$ , for  $t < 0, r \geq 0$ . An unspecified perturbation occurs at  $t = 0$ , and for times of interest  $t > 0$  it does not affect regions remote from the  $r = 0$  boundary. Hence  $F(r,t) = F_0$ , for  $t \leq \tau, r = \infty$ , and in the case of planar geometry they derive the solution:

They then go on to consider the problem of 1D heat conduction in a semi-infinite plane, and so look at the heat equation in the form:

with appropriate boundary conditions of  $T(r,0) = 0$  and  $T(\infty,t) = 0$ . The heat flux sought is

which they get from their earlier solution for  $\partial F(r,t)/\partial r$  by putting  $T$  for  $F, K/\sigma$  for  $\kappa$ , and using

Because this result, Oldham and Spanier's equation 11.2.10 is closely related to equation 43 in part I of the present ms, I think that it should be explained clearly whether i) the present paper is effectively an illustration of Oldham and Spanier's result in the EBM context, or ii) whether it offers a derivation in a domain to which Oldham and Spanier's result did not apply. Either situation will be important and publishable but readers need to know which applies. Interestingly, Oldham and Spanier noted that the equation had been obtained by Meyer in 1960 in a Canadian NRC technical report ("A heat-flux-meter for use with thin film surface thermometers"), but rather than being written as a half order derivative it was then given in the alternative integral form:

without explicitly using fractional calculus. It was thus known in the heat transfer context even before the first EBMs were derived, in a sense reinforcing the present author's point.

C3

Au: There are several important differences w.r.t. to Oldham's results.

a) Oldham considers only a single spatial degree of freedom  $r$  corresponding to either the "zero-dimensional" model (eq. 22 part 1) or cylindrical or spherical geometries that we do not consider. He nowhere considers fractional space-time operators as in part 2. I.e. he neither treats homogeneous operators but with inhomogeneous boundary conditions, nor does Oldham treat inhomogeneous media (inhomogeneous transport operators). In other words essentially all of part 2 (eq. 3 and later) is outside his scope.

b) Our boundary radiative-conductive boundary conditions are special cases of "Robin" boundary conditions i.e. they involve a linear combination of the field and its normal gradient over a surface. Although Robin boundary conditions are occasionally used in insulating boundary condition problems in convective diffusive equations, they are not identical to the radiative-conductive conditions used here. Oldham mentions Cauchy, Neumann and Dirichlet boundary conditions and says that "any other type" could be used. In other words he realized that his formalism was more general than the applications he developed, but did not pursue these. I will add this information in the revised ms.

c). Although it is not essential, Oldham's application of the method was to use more or less standard boundary conditions (Dirichlet) and then deduce the heat flux across surfaces from this. As far as I can tell, since then, this is almost invariably the way the method has been applied.

d) A final more minor difference is that we also treated the Weyl derivative and used the corresponding Fourier techniques.

We will add references to these difference in the new ms.
